V. 1-2
1912

Journal of the Society of Chemical Industry.

INDEX OF VOL. XV.—1896.

INDEX OF AUTHORS' NAMES.

N.B.—In this Index (P) indicates that the matter referred to is an abstract of a Patent.
Titles of new books are indicated by “ ”.

LIST OF ABBREVIATIONS.

App:	Apparatus	Estim:	Estimate,-tion,-ing	Precip:	Precipitation,-ing
Applic:	Application,-able	Evap:	Evapora,-tion,-ing	Prep:	Prepara,-tion,-ing
Artif:	Artificial	Exam:	Examine,-ation,-ing	Prev:	Prevention,-ing
Atmos:	Atmospheric,-sphere	Extrac:	Extraction,-ing	Prod:	Produce,-tion,-ing
Aurif:	Auriferous	Ferment:	Fermentation,-ing	Protect:	Protection,-ing
Auton:	Automatic	Forma:	Formation	Purif:	Purification,-ing
Charac:	Character,-istic	Gen:	Generation,-ing	Qual:	Quality,-tative
Chem:	Chemical,-s,-istry	Impt:	Improvement,-s	Quant:	Quantity,-tative
Co:	Company	Inf:	Influence	Rectif:	Rectification,-ing
Col:	Colours,-ation,-ing	Manuf:	Manufacture,-ing	Reg:	Regulation,-ing
Collect:	Collecting,-tion	Mat:	Matter,-s	Separ:	Separation,-ing
Comp:	Composition,-pound	Mech:	Mechanism,-cal	Soc:	Society, Societe
Concent:	Concentration,-ing	Min:	Mineral,-s,-ogy	Sp. Gr:	Specific Gravity
Const:	Construction,-ing	Modif:	Modification,-ing	Temp:	Temperature
Contrib:	Contribution,-ing	Nat:	Natural	Titanif:	Titaniferous
Cultiv:	Cultivation,-ing	Org:	Organic,-ism	Util:	Utilisation,-ing
Decomp:	Decompose,-ition,-ing	Photo:	Photography,-graph-ic	Veg:	Vegetable,-tion
Detect:	Detection,-ing	Physiol:	Physiology,-ical	Volum:	Volumetric
Determ:	Determine,-ation,-ing			Vorn:	Normals
Diam:	Diameter				
Discrim:	Discriminate,-tion,-ing				
Distill:	Distillate,-tion,-ing				

A

	PAGE
Abell, W. P. Megass and Refuse Furnaces	210
Abney. <i>See</i> Thorpe	798
Ach, L. <i>See</i> Fischer	213
Ackermann, E. Albuminoids and Phenols, Reactions of	221
Ackermann, E. and V. Cotton Warps, Alsatian Methods of Sizing	580
Ackermann, F. P. J. Acetylene Gas, App: for Prod: (P)	796
Actienges: für Anilin Fab: Col: Mat: Dyeing Yellow with Mor-	
dants, Manuf: of (P)	351
Col: Mat: Manuf: of Azo Black and Grey (P)	446
Col: Mat: Manuf: of Direct-dyeing (P)	110, 270
Col: Mat: Manuf: of Direct-dyeing Azo (P)	447
Col: Mat: Manuf: of Polyazo (P)	270
Col: Mat: of Rosinduline Series, Manuf: of (P)	587
Dyes, Manuf: of Blue-Black Azo (P)	29, 30
Sulphonc Acids, and Col: Mat: therefrom (P)	270
Triphenylmethane Series, Manuf: of Derivatives of (P)	803
Action Ges: Dynamit Nobel. Explosive, Manuf: of	829
Adeney, W. E. Water, Fermentative Changes in	463
Adgie, W. <i>See</i> Yeaton	185
Adiasiewitsch, A. W. Petroleum and Bitumen, Prep: of Solid Resins, &c. from	346
Adlam, W. Pneumatic Maltng and App: therefor (P)	466
Ahrens, C. <i>See</i> Dennstedt	187
Ahrens, F. B. Nitriles, Conversion of, into Amines by Electro-	
lysis	725
Aitken, R. Fibres or Yarns, &c., Oiling or Waxing Animal (P)	
Paper, Treatment of (P)	196
Wood, Treatment of, for Preserving and Colouring (P) ..	468
190	
Albert, H. Carbonaceous Absorbent, Manuf: of (P)	43
Albrecht. Accidents in Dye Works, Prev: of	825
Albright, G. S. <i>See</i> Crowther	357
Alers-Hankey, L. Water, App: for Purif: (P)	733
Alessandri and Guassini. Nitrates in Water, Detect: of	216
Alexander, D. W. <i>See</i> Knees	208

	PAGE
Alexander, J. C., and Beveridge, R. C. Kerosene Shale, Treat-	
ment of (P)	347
Alexandre, F. Acetylene Gas, Prod: of (P)	796
Alimonda, S. Tanning Skins, Hydraulic Process for (P)	912
Allen, A. H. Caffeine, Discus: on Determ: of, in Tea	96
“Commercial Organic Analysis”	623
Cream of Tartar, Comp: and Analysis of	680
Hydrofluoric Acid, Prep: of Pure	378
Quinine, Titration of	386
Vinegar, White Wine	823
Allen, G. Y. <i>See</i> Perkin	647
Alliott, J. B. Evap: App: (P)	186
And Paton, J. McC. C. Furnaces for consuming Refuse (P)	
289	
Allman, W., and Millward, J. Injectors, &c. for forcing	
Gaseous Liquids (P)	341
Alsberg, M. Gold Ores, Discus: on Chlorination of	330
Potash, Discus: on Carbonate of	877
Altshul. Sugar, Presence of Lead in Beetroot	125
Altshul, J. Fatty Bodies, Action of Sulphur on Unsaturated	
Vanillin, Prep: of	282
596	
Aluminium Ind: Actienges: Aluminium and Magnesium,	
Manuf: of Granulated (P)	658
Amsel, H. Chrome Yellow and Chrome Red, Analysis of	830
Linseed Oil and Varnish, Exam: of	222
Anderlik, K. Mucilage and Dextrins from Osmose Process ..	
286	
Anderson. Bordeaux Mixture, Discus: on	335
Anderson, A. K. Y., and Mackintosh, J. Hides and Skins,	
Treatment of, in Manuf: of Leather (P)	208
Anderson, J. C. Wool Cleansing (P)	353
Anderson, W. C. Coke, Sp: Gr: and Porosity of	29
Andés, L. E. Varnishes, Drying of	461
André, G. <i>See</i> Berthelot	821, 822
André, G. G., and Curtis, C. H. Explosives, Manuf: of Safety	
(P)	615
Andreas, E. Electricity, Prod: of, by Chem: Means	908
Andreasch, F. Ferment: Phenomena in Tan Liquors	910
Andreoli, E. Drying Oils, Treatment of (P)	123
Gold and Silver, Electro-Deposition of (P)	726
Ozone, App: for Prod: of (P)	726

	PAGE		PAGE
Androsi, E. and S. W. Amalgams, Electrolytic Prod. of (P)	726	Baird, H. See Kinder	367
Andrews, E. R. See Meldola	28	Balatsch, E. and others. Wool and Hair Waste, Cleansing (P)	353
Andrews, F. G. Aluminium Alloys	275	Baldo, G. B. Caustic Soda, Hydrogen, and Chlorine, by Electrolytic Process (P)	198
Andrews, J. See Woolf	907	Electrolytic Processes and App. therefor (P)	458
Andrews, L. Alloys of Lead, Tin, Antimony, and Arsenic, Analysis of	217	Balland, Aluminium Vessels	118
Andrews, W. W. Blowpipe Analysis	829	Bread, Nitrogenous and Min. Mat. in	130
Angel, H. R. Lead, Extract of, from Sulphide Ores (P)	119	Gluten in Meal, Determin. of	622
Antropoff, R. v. See Seyffert	367, 365	Rice Imported into France, Composition of	130
Appert, L. Glass, Function of Alumina in Comp. of	357	Ballantine, A. T. Refrigerating Machines (P)	262
Appleby, E. and Harris, H. F. Acetylene Gas, App. for (P)	796	Bals, M., and Gurovits, E. Amorphous Phosphorus for Matches, Primings, &c. (P)	471
Appleyard, J. R. See Walker	650	Bamberger, E., and Meimburg, P. Col. Mat., Observations on Azo	193
Archbutt, L. Air in Water, Discuss. on	864	Bamford, S. B., H., sen, and jun., and J. Cooling App. (P)	528
Ether, Determin. of Pressure of, in Closed Vessels	85	Bandsept, A. Bunsen Burners, Incand. Burners, &c. (P)	704
Ether, Determin. of Pressure of, Discuss. on	86	Banner, S. Oils, Fats, &c., Oxidation of Fixed (P)	123
Iron, Discuss. on Corrosion of, by Raw Tar	326	Banziger, E. See Gnehm	535
Nitric Acid, Ignition of Sawdust by	84	Barany, J., and Mucke, J. Vaporising Burner for Oil (P)	413
Nitric Acid, Ignition of Sawdust by, Discuss. on	85	Barber-Starkey, W. J. S. Electrical Storage Batteries (P)	277
Oil, Discuss. on Evap. Test for Min. Lub.	328, 328	Barbiero, Mydrol	919
Oil, Evap. Test for Min. Lub.	326	Barbier, P., and Bouveault, L. Citronellal and Rhodinal	373
Arlt, O. Electrolysis, Process and App. for. (P)	908	Licarol, Licarhodol, and Limonol, Action of Gaseous HCl on	613
Armstrong, H. E. Nitrazin, Discuss. on	773, 774	Rhodinal, and its Transformation into Menthone	373
Turpentine, Report on Two Borneo	363	Rhodinol, Constitution of	409
And Wynne, W. P. 2:15 (Naphthylaminesulphonic Acid and corresponding Chloro-naphthalene-sulphonic Acid, No. 15)	169	Rhodinol from Oil of Pelargonium and Otto of Roses	373
And Wynne, W. P. Tri-Derivatives of Naphthalene, No. 15	169	Barclay, J. W. Soap, Manuf. of (P)	817
Arndt, E. M., and Bruyn, G. de. Stone, Manuf. of Artif. (P)	452	Barillot, E. Calcium Acetate, Analysis of Commercial	680
Arndt, M. Gases, App. for Registering Weight of (P)	472	Charcoal, Methyl Alcohol, and Acetic Acid yielded by different Woods	346, 584
Arnheim, A. Di-iodomethyl Salicylate	469	Wood, Products of Distill. of	347
Arnold, J. O. Iron, Influence of Carbon on	453	Barin, Gould, E. S. See Smith	690
Arth. Coal, Calorific Value of	794	Barnard, E. Blast Furnace, Obstructions in the	811
Aschman, C. See Schmeltzer	285	Barnes, J. Chronic Acid, Estim. of Org. Mat. by	82
Aschner, F. H. See Young	443	Titanium Oxide as Mordant for Wool, Discuss. on	422
Ascough, J. Antiseptic Prep. for Preserv. of Foodstuffs (P)	660	Titanium Oxide as Mordant for Wool	420
Soaps and Comp. Manuf. of Antiseptic (P)	661	Zirconium and Cerium Oxides, Note on	420
Ashcroft, E. A. Zinc Ores, Treatment of (P)	648	Water free from Ammonia, Prep. of	254
Ashmore, Benson, Pease, and Co. See Pease	261	Barnett, H. T. Gas Batteries (P)	38
Ashworth, A. Mordants, Fixing Metallic, on Fibres (P)	901	Barnsley, E. W. Varnish, Manuf. of (P)	549
Athamaseco. Basic Nitrates	835	Baron, N. Petroleum, Increasing Lighting Power of (P)	191
Atkins, T., and Harris T. A. Filtering App. (P)	102	Barr, A., and Stroud, W. Prod. of High Vacuo, and App. for (P)	611
Atkinson, H. F. Vapour or Gas, App. for Injecting into Furnaces (P)	706	Barr, L. See Holman	655
Atkinson, J. E. Acetylene Gas, App. for Manuf. of (P)	705	Barratt, A. A. Photographs in Relief in Gold, &c.	741
Auchy, G. Iron, Determin. of Sulphur in Pig	381	Bartel, A. Water for Tanneries, Valuation of	284
Manganese, Determin. of, in Steel	677	Barth, M. Wines, Investigation and Valuation of Sweet	367
Manganese, Volum. Estim. of	220	Barthel, G. Aldehydes, Prep. of (P)	668
Aufrecht, Petroleum, Determin. of Sulphur in	680	Bartholomew, W. See Watson	36
Autenrieth, W. Luteol, a New Indicator	216	Bartlett, F. L. Furnaces and Flues, Improving Combustion in (P)	438
Avellis, E., and Koster, E. Leather, Prep. of Chrome-dressed, for Dyeing (P)	818	Baskerville, C. Copper and Concent. Sulphuric Acid, Reactions between	201
Aykroyd, H. E. See Richardson	171, 328	Basle Chemical Works. Alkylglycollic Acid Derivatives of p-Amidophenol Ethers, Manuf. of (P)	611

B

Babenek, S. C. See Campbell	905	Baudouin, L. M. H. R., and Schribaux, P. E. L. Liquids, Concent. of (P)	709
Bablich, H., and Perkin, A. G. Monn	445	Bauer, E. Potash, Estim. of, as Potassium Platinochloride	473
Bach, A. Hydrogen Peroxide, New Test for	157	Bauman, Steffen's Sulphuration Process	822
Bachelerie, C. L. Orz. Substances, Preserving (P)	667	Baumann, R. Metal Turnings and Scrap, Smelting of (P)	203
Bach, F. G. Coal-Slime, Treatment of, and App. for (P)	25	Baumert, P. Hydrocarbons as Fuel, Treating Liquid (P)	583
Bachmann, J. F., and others. Electrical Glow Lamps, Incand. Body for (P)	795	Bau, A. Opoponax	373
Badley, E. F., and others. Bituminous Comp. (P)	102	Bauwaerts, E. F. J. C. Acetylene Gas, Purif. of (P)	644, 645
Badische Anilin und Soda Fabrik. Col. Mat. New Basic (P)	28	Bayer, A. See Balatsch	353
Col. Mat. New Mordant-Dyeing Yellow (P)	647	Bayer, K. J. Potassium Chlorate, Manuf. of	32
Col. Mat. of Anthraquinone Series, Prod. of Black (P)	587	Bayley, J. C. Acetylene Gas, App. for Gen. Storing, and Purif. (P)	531, 795
Diazo Comp. and Azo Dyes, &c., Manuf. of (P)	332	Baynes, H. K., and Chem. Electrolytic Syndicate. Alkaline Nitrates, Decompos. of (P)	356
Dyes, Manuf. of Azo- (P)	28	Beadle, C. Paper, Animal Sizing of	370
Dyes, Manuf. of Dis- and Polyazo (P)	588	Papers, Cost of Drying Tub-sized	290
Dyes of Benzidine Series, &c., Manuf. of Azo (P)	195	Wood Pulp, Discuss. on Moisture in	244
Dyes of Benzidine Series, &c., Manuf. of Polyazo (P)	351	And Dahl, O. W. Cellulose, Increase in Temp. of, on Absorption of Atmos. Moisture	352
Dyes, Prod. of Polyazo, on Veg. Fibre or Silk (P)	351	Bech, R. Cement, Hardening of Portland, in Sea Water	358
Rhodamine Series, Products related to, Manuf. of (P)	352	Bechi, de. See Friedel	268
Badon, J. Sheet Glass, Substitute for (P)	275	Beckmann, E. Honey, Exam. of	622
Baender, M. See Markus	197	And Eickelberg, H. Methone: Its Conversion into Thymol	470
Baermann, A. Incand. Lamps for Vaporised Liquid Fuel (P)	105	Beckurts, H. Ergot, Valuation of	223
Baier, J. Whalebone, Manuf. of Imitation (P)	462	Bedford, J. E., and C. S. Linoleum, &c., Printing Inlaid Patterns on (P)	540
Bailey, C. S. Paint, Comp. for Removing (P)	363	Bedson, P. P. Remarks on Chairman's Address. Newcastle Section	861
Bailey, H. P. See Louton	132	Beebe, C. B. See Chamberlain	704
Bailey, R. D., and Ford, L. P. "Draft" or Spent Grains, Util. of (P)	607		
Bailey, W. H. Furnaces for Heating Metal (P)	546		
Bailhache. See Riviere	606		
Bailly, A. "L'Industrie du Blanchissage et les Blanchisseries."	591		
Bair, M. A. Primary Electric Batteries (P)	39		

	PAGE
Beeson, J. L. Sugar Cane, Amines in Juice of.....	663
Behrens, H. Cinchonidine and Homocinchonidine: Their Microchemical Distinction	372
Beilby, G. Flash Point for Min: Oil, Discuss: on.....	335
Bein, W. Electrolysis without Diaphragms	276
Belar, A. Red Wines, Detect: of Foreign Col: Mat: in.....	619
Bell, G. and G. W. Liquids, App: for Electrolytic Decom: of (P).....	908
Bell, J. See Hancock.....	111
Beltzer, Bichromate, Recovery of, from Spent Aniline Black Liquors.....	650
Benda, L. See Gnehm.....	707
Bender, A. and Erdmann, H. "Chemische Präparatenkunde".....	225
Benfey, H. See Green.....	709
Benfield, T. Lead Oxide, Manuf: of (P).....	207
Benker, C. F. Sulphuric Acid, Manuf: of (P).....	197
Bennett, A. A. and Placeway, L. A. Halogens, Quant: Determ: of.....	674
Bennett, C. G. T. and others. Galvanisers' Flux Skimmings, Recovery of Ammonia, &c. from (P).....	205
Benneville, J. S. de. Iron Carbides, Some Alloys with.....	453
Berge, H. J. N. Water, Purif: of Drinking (P).....	733
Berger, C. Cement Testing.....	380
Berger, J. Shabbing Dyeing, Dyes and App: for.....	196
Bergmann, Cyanogen from Ammonia.....	543
Bergmann, C. Jute, Retting or Steeping (P).....	353
Bergmann, E. Cyanogen, Formas: of, from Ammonia.....	419
Berzold, A. D. and Falk, I. H. Bean Flour, Manuf: of (P).....	289
Berlin Anhaltische Maschinenbau-Aktienges: Gas, Prev: of Freezing of (P).....	532
Bernard, J. See Engel.....	381
Bernstein, A. Beverage from By-Products of Dairies, Prep: of (P).....	608
Berastain, B. See Polylitzin.....	107
Bersey, W. C. See Fitzgerald.....	361
Berthelot and André. Arabinose, Action of Water and Acids on Sugars, Prod: of Carbon Dioxide during Decom: of.....	822
Berthelot, P. E. M. and Vieille, M. Acetylene, Explosive Properties of.....	793
Bertram, J. and Gildemeister, E. Geraniol and Rhodinol.....	202
Bertrand, C. E. Kerosene Shale of New South Wales.....	797
Bertrand, G. Laccase: its Oxidising Power.....	561
Lyxomic Acid and Lyxitol.....	605
Oxydase or Soluble Oxidising Veg: Ferment:.....	565
Pentose, A New.....	605
And Malleve, A. Pectase, its Occurrence and Prep:.....	127
Bertrand, P. H. Iron, Prod: of Magnetic Oxide on (P).....	10
Beschetznick, Mortar, Strength of Common.....	36
Besson, A. Gas Burners, Incandescent (P).....	344
Bessonoff, S. See Yagu.....	23
Best, T. T. and others. Chlorine, Manuf: of, from HCl Gas (P).....	594
Corrosive Liquids, App: for Pumping (P).....	22
Bettoni, A. See Camiz.....	123
Bevan, E. J. Artif: Silk, Discuss: on.....	319
See Cross.....	300, 317, 386
Beveridge, J. Steam required to Dry a Ton of Pulp, Calculation of.....	251
Wood Cellulose Industry of Scandinavia.....	249
Beveridge, R. C. See Alexander.....	347
Biedermann, R. "Chemiker-Kalender, 1897".....	835
Bielefeld, M. Explosives containing Saltpetre, Manuf: of (P).....	921
Biermann, A. See Puller.....	148
Biermann, J. Fur, Manuf: of Artif: (P).....	730
Biérix, A. Col: Mat: from Dibromogallie Acid.....	318
Dibromogallie Acid, Action of Nitrosodimethylamine on.....	538
Bilton, E. Earthenware, Manuf: of. (P).....	450
Sinet, P. Phenols, Toxicological Action of the.....	479
Birch, W. Shulze, App: for Separ: Solid or Semi-Solid Substances from (P).....	553
Birchall, C. F. B. See Picking.....	275
Bird, F. C. J. Formaldehyde, Detect: and Quant: Estim: of.....	833
Bird, S. G. and Wright, J. Cement Concretes, Manuf: of (P).....	452
Bird, T. See Hargreaves.....	113
Birnbaum, K. See Bolley.....	302
Bishop, Flash Point for Min: Oil, Discuss: on.....	335
Bishop, M. W. Oils, Determ: of Degree of Oxidation of.....	475
Blackman, H. Bleaching Agents, Electrolytic (P).....	355
Blackmore, H. S. Metallic Comp: Prod: of (P).....	658
Blackwell, L. Bleaching Powder, Prod: of, from Sodium Chloride (P).....	652
Blair, A. A. "The Chemical Analysis of Iron".....	926
Blake, M. Sugar, &c., Machinery for Melting (P).....	528
Blake, R. F. See Letts.....	921
Biasdale, W. C. Oils, Physical and Chem: Properties of Californian.....	205
Bleier, O. Gas Analysis, App: for.....	619, 672
Gas Burettes, Modif: of the Hempel and Bunte.....	294

	PAGE
Bloch, L. and Schwartz, C. Aniline Black, White and Col: Resists on.....	710
Bloomfield, J. C. Plaster, Manuf: of (P).....	452
Blount, R. Oxygen in Commercial Copper, Determ: of.....	296
And Bloxham, A. G. "Chemistry for Engineers and Manufacturers".....	225, 926
Bloxham, A. G. See Blount.....	225, 926
Blumenfeld, B. Asbestos Filters (P).....	261
Blythe, W. S. See Wolf.....	594
Bode, P. Gas-Burners, Incandescent (P).....	803
Bodenbender, H. and Rydlewski, N. Sugar Beet, Manuring with Potash Salts.....	12
Boedtker, E. Aluminium Chloride, Action of, on Benzine.....	645
Boehlinger, C. F. & Soehne. Vanillin, Manuf: of (P).....	710
Boehlinger, C. H. Zinc Lactate as Cotton Mordant (P).....	804
Boissacrand, P. Liquids, Sterilising and Purif: (P).....	132
Bolley, P. A. and Birnbaum, K. "Handbuch der Chemischen Technologie".....	502
Bomer, A. Albumoses, Zinc Sulphate a Precipitant for.....	130
See König.....	130
Bond, P. T. Liquids, Protec: of Sterilised (P).....	824
Bone, W. A. and Cain, J. C. Acetylene, Explosion of.....	889
Bonehill, E. Furnaces, Puddling and Reheating (P).....	599
Bonnet, A. Vegetable Fibres, Direct Fixation of Metallic Oxides on.....	111
Borchers, W. Electricity, Uses of, in Metallurgy.....	278
"Elektro-Metallurgie".....	112
Galen containing Zinc, Working of.....	362
Metals, Electric Furnaces for.....	908
See Nerst.....	565
Bordas and Genin. Milk, Congealing Point of.....	715
Borcius, A. See Zimmermann.....	101
Borland, W. D. Explosives (P).....	214
Borrmann-Zix, F. Superheated Steam, Prod: of (P).....	528
Borritrager, A. Bergamot Oil, Exam: as to Purity.....	223
Bergamot Oil, Proof of Purity of.....	739
Iron, Colorimetric Estim: of Traces of, in Wine.....	562
Wine, A Green-coloured Secondary.....	732
Boseley, L. K. See Richmond.....	382
Bosselaar, J. M. and Elshout, J. F. M. van der. Gas, Manuf: of Petroleum (P).....	104
Boter, A. Acetylene Gas, App: for Producing (P).....	726
Bothamley, C. H. Ferrous Oxalate Development, Use of Clearing-Bath after.....	293
Bouchardat, G. and Tardy. Anise, Russian Oil of.....	374
Bouffard, A. Ferment: (Wine), Determ: of Heat Liberated in Alcoholic.....	128
Boulet, J. C. R. G. Fermented Products, Manuf: of (P).....	606
Bour, H. N. Feathers, Method of Dyeing (P).....	804
Bourbott, C. Fuel, Uninflammable Wick for Liquid (P).....	266
Bourlez, V. Blackboards, Liquid Composition for (P).....	602
Bourot and Jean. Butters, Digestibility of Coconut and Cows'.....	824
Bouquetot, E. Mushrooms, Action of Oxidising Ferment of.....	683
Phenols Insoluble in Water, Action of Oxidising Ferment of Mushrooms on.....	719
Rulinose, Hydrolysis of, by Soluble Ferments.....	465
And Hérissey, H. Melezitose, Hydrolysis of, by Soluble Ferments.....	835
Bouveault, L. See Barbier.....	373, 373, 373, 469, 613
Bovril, Ltd. See Johnston.....	211
Bowen. Spain, Excessive Manuring in.....	602
Bower, A. W. F. See Fowler.....	741
Bower, H. Gas Liquor, Treatment of (P).....	274
Prussiates, Manuf: of (P).....	274
Bowling, J. Coking Processes (P).....	582
Bowman, F. H. and others. Alkali Furnaces, &c., Feed Hoppers for (P).....	807
Boyd, H. New Explosive.....	823
Boynton, E. S. Durable-Fluid Galvanic Batteries (P).....	121
Galvanic Batteries (P).....	39, 121
Bracey, B. See Bennett.....	203
Brackelsberg, C. A. Hot-blast Blocks and Bricks (P).....	596
Bradburn, J. A. Alkali, Manuf: of, by Ammonia Process, &c.....	877
Bradbury, J. Breweries, Util: of Waste Products from (P).....	824
Bramham, W. Photography, Discuss: on Chromatic.....	404
Braunwell, R. S. O. Oils, Injection or Ejection of Min: and App: therefor (P).....	194
Brand, A. Manganese Bistres, Albumin Discharges on.....	449
Brandell, P. Pumps (P).....	24
Branson, F. W. X Rays, Estim: Intensity of.....	865
Bratsch, C. F. F. French Polish, &c., Imppts: in (P).....	298
Bruchach, G. Pyrometer for Blast-Furnace Tuyeres.....	904
Braumann, M. and A. Vegetables, &c., Preservation of (P).....	211
Braun. Bone Meal, Phosphoric Acid in.....	550
Fluorine in Phosphates, &c., Determ: of.....	474
Braun, L. Maltose, Determ: of, in Worts.....	680
Brerley, H. Auto-Pneumatic Stirrer.....	744

INDEX OF SUBJECTS.

N.B.—In this Index, (P) indicates that the matter referred to is an abstract of a patent; (T.R.) indicates that the matter referred to is in the Trade Report.

A

	PAGE
Absinthe, Detect. of Adulteration in. (Niviere and Hubert)...	137
Absorbent, Mannf. of a Carbonaceous. (P) Albert.....	43
Accidents and Dangers in Dye, Print, and Bleach Works, (Albrecht).....	825
Accumulator for Spraying App: (P) Rusden and Eeles.....	614
Accumulators, Persulphuric Acid in Lead. (Elbs and Schonherr).....	277
See under Batteries, Secondary.	
Acetanilide, Phenacetin, Quinine Sulphate, &c., Identification of. (Hyde).....	297
Acetates, Purif. of. (P) Scott and Henderson.....	273
Acetic Acid, Action of, on Sugar Solutions.....	849
Acid and Benzene, Formula of Layers in Mixtures of. (Linebarger).....	300
Acid, Mannf. of Acetone and Acetone-Chloroform from. (Squibb).....	612
Acid, Obtaining, from Pyroigneous Salts. (P) Thompson. From von der Lund.....	357
Acid, Quant. of, yielded by Different Woods. (Barillot).....	584
Acid and Wine Yeasts. (Lafar).....	128
Acetone, Determ. of. (Kramer).....	299
Determ. of, in Wood-Spirit and Crude Acetone. (Klar) ..	299
Processes and App: for Making Pure. (P) Porsch.....	374
Use of, in Technical Analysis of Asphaltum. (Peckham) ..	298
And Acetone-Chloroform, Mannf. of. (Squibb).....	612
-Chloroform, Mannf. of, from Acetic Acid. (Squibb).....	612
Acetones, Use of, in Photo. Development. (Lumiere and Seyewetz).....	926
Acetophenonephenetide, Prop. of. (P) Valentiner.....	50
Acetylene, Action of, on Iron, Nickel, and Cobalt. (Moissan and Moreau).....	530
And Air, Experiments on the Combustion of. (Le Chatelier).....	793
And Air, Limits of Explosibility of. (Clowes).....	418
And Calcium Carbide, Carriage of, in Germany. (T.R.) ..	228
Combustion of. (Le Chatelier).....	188
Commercial Value of.....	343
Electrical Conductivity of. (Bredig and Usoff).....	748
Explosion, A Fatal. (T.R.).....	755
Explosion of, with Oxygen. (Bone and Cain).....	889
Explosive Properties of. (Berthelot and Vieille).....	793
For Lighting. (T.R.).....	753
For Lighting, Report on the Prep. and Use of. (Vieille) ..	794
Gas, App: for Prod. of. (P) Ackermann.....	796
Gas, App: for Prod. of. (P) Atkinson.....	795
Gas, App: for Prod. of. (P) Bayley.....	795
Gas, App: for Prod. of. (P) Boul. From Fuller.....	892
Gas, App: for Prod. of. (P) Clarke.....	531, 796
Gas, App: for Prod. of. (P) Exley.....	531
Gas, App: for Prod. of. (P) Farnsworth.....	532
Gas, App: for Prod. of. (P) Gearing.....	25
Gas, App: for Prod. of. (P) Haddan. From Boter.....	796
Gas, App: for Prod. of. (P) Kon.....	893
Gas, App: for Prod. of. (P) Rickman. From Pintsch.....	892
Gas, App: for Prod. of. (P) Sardi.....	892
Gas, App: for Prod. of. (P) Thorp and Marsh.....	532

Azones, Basic and Phenolic. (Möhlau and Uhlmann)	585
Azonium Comp. Conversion of Phenosafranine and Resindis-	
line into Parent. (Kehrmann)	802
Azophenotols, Reduction of. (Meyer)	27

B

Bacillus, A Viscous, in English Beer. (Vandam)	129
Bacteria, Reduction of Nitrates by. (Richards and Rolfe)	667
Bacterium Aceti Hansen and Bacterium Pasteurianum Han-	
sen, Inf. of Temp. on Growth of. (Lafar)	44
Bagasse, Deterior. of Fibre in. (Shorley)	603
Method and App. for Treatment of. (P) Perichon	551
Bakeries, Petroleum Residues Used in. (Dunbar)	368
Balance, Auxiliary Assay	377
Ballarat, Gold Milling at. (Wingate)	869
Barium and Calcium Ferrocyanides, Use of Org. Bases in Prep.	
of. (Walker)	273
Tetrachromite. (Dufau)	402
Barley and Malt, Phosphoric Acid in. (Fernbach)	621
Colour of. (Schonfeld)	731
Barrel, Ten-Ton Chlorination	36
Bases Manuf. of New Diamond. (P) Inray. From The Farb-	
vorm. Meister, Lucius, and Bruning	647
Basic Process, Phosphoric Slags from the. (Jean)	550
Bath for Electro-Plating. (P) Pitt. From Hollingshead	459
Batoum, Analysis of Gold from. (Tchernik)	117
Export of Illuminating Oil from. (T.R.)	685
Batteries, Various:—	
Double-Fluid Galvanic. (Boynton)	121
Electric. (P) Shrewsbury and others	550, 361
Electrical Primary. (P) Whittemore	908
Galvanic. (Boynton)	121
Galvanic. (P) Gordon	38
Galvanic. (P) Iwanowski	278
Galvanic Tubular. (P) Boynton	39
Gas. (P) Barnett	38
Oxidising Lead for Const. of Secondary. (P) Leitner	277
Prep. of Lead Chloride for use in Storage. (P) Davis	357
Primary. (P) Levett and others	38
Primary. (P) Rowbotham	39, 39, 46
Primary. (P) Rowbotham and Levett	38, 38
Primary Electric. (P) Bair	39
Primary Electric. (P) Entwistle. From Smith and	
Baring-Gould	609
Secondary. (P) Barber-Starkey	277
Secondary. (P) Falero and Lumley	458
Secondary. (P) Fane and King	121
Secondary. (P) Gulcher	278
Secondary Dry. (P) Junger	609
Secondary. (P) King	547
Secondary. (P) Marchant and Woolley	38
Secondary. (P) Pirsch	38
Secondary. (P) Pross	908
Secondary. (P) Rooney	121
Secondary Voltaic. (P) Epstein	204
Secondary Voltaic. (P) Fitzerald and Bersey	861
Battery Electrical. (P) Jacques	458
Battery Cells, Plates, Elements, Solutions, &c.:—	
Anodes, Manuf. of Carbon. (P) Jensen. From Cappelén	659
Active Material for Secondary. (P) Dannert and others	659
Active Material for Secondary and Primary. (P)	
Schanschiff	277
Cell of High and Constant E.M.F. (Marisot)	129
Cells, Const. of Galvanic. (P) Vogt	121
Cells, Electrolytic or Galvanic. (P) Lake. From Hoepfner	816
Cells, Form. of Persulphuric Acid in Storage. (Schoop)	360
Cells, Galvanic Dry. (P) Jungnickel	39
Diaphragms for Electrolytic Purposes. (P) Bronthead.	
From La Soc. Anon. des Anciennes Salines Domaniak	
de l'Est Actien Gesellschaft	458
Electrode. (P) Beck. From Johnson and Robertson	547
Electrode Plates for Secondary. (P) Lucknow	360
Electrodes. (P) Leitner and Reicher	121, 204
Electrodes Carbon. (P) Hoepfner	659
Electrodes for Electrolytic App. (P) Kellner	816
Electrodes for Secondary Batteries. (P) Leitner	361
Electrodes for Secondary Batteries. (P) Majert	547
Electrodes for Voltaic Batteries, Manuf. of. (P) Epstein	725
Electrodes, Manuf. of Platinum Tubular. (P) Heraeus	909
Elements for Voltaic. (P) Hulin	39

Battery Cells—cont.	
Filling Paste for Accumulators. (P) Linde	547
Plates for Secondary Galvanic Batteries. (P) Marschner	968
Plates for Secondary Batteries. (P) Ribbe	600
Plates, Manuf. of, for Batteries. (P) Körner	816
Plates, Manuf. of Positive, for Secondary Batteries. (P)	
Weise	547
Bean Flour, Manuf. of. (P) Lake. From Beretold and Falk	289
Behrme. (Scholtz)	737
Beef-fat in Lard. Microscopic Detect. of. (Gladding)	560, 881
Beer, Cause of Musty Taste in. (Windisch)	914
Charging with Gas. (P) Borlt. From Hofmann	45
Detect. of Small Amounts of Fluorine in. (Windisch)	561
Ferment, Multiplication of Yeast during. (Schonfeld)	552
Fining of, by Light. (Reinke)	465
"Flour Dressing" in its Relation to. (Glendinning)	45
Glycerol in. (Sostegni)	680
Increasing Stability of. (P) Gronwald	733
Japanese. (Makel)	823
Malt Extract for Col. and Flavouring. (Theurer)	915
Occurrence of Pentosins and Pentoses in. (Mohr)	140
Pasteurisation of. (Van Laer)	44
Prep. of a Light. (Reinke)	607
Preservation of. (P) Lippke	915
Priming Material for. (P) Free	824
Viscous Bacillus in English. (Vandam)	129
Beet Juice, Simultaneous Determ. of Min. and Org. Acids in.	
(Sidersky)	922
Paup. Loss in Dry Solids of, on Pressing and Drying	912
Beetroot, Estim. of Sugar in. (Pellet)	746
In Germany. (P) Bort. From Hofmann	366
Juice, Determ. of Free Alkali in. (Cotrat)	832
Juice, Gelatinous Separ. in. (Glaser)	209
Juice, Simultaneous Determ. of the Org. and Min. Acidity	
of. (Sidersky)	603
Manuring with Potash Salts. (Bodenbender and Ryd-	
lewski)	42
Loss of Sugar during Preservation of. (Strohmer)	550
Belgium, Alcohol Tax in. (T.R.)	939
Manuf. of Portland Cement in	809
Manuf. of Matches in	368
Benzaldehyde Action of, on Chloroacetylpyrazolol. (Kessel-	
kaul and Von Kostanecki)	646
Chlorination Products of. (Gnehm and Buzinger)	555
Benzamide- α -Sulphonic Acid and Saccharin, Ac. Manuf. of.	
(P) Newton. From The Farb. vorm. Bayer and Co.	292
Benzene, Action of Aluminium Chloride on. (Boedker)	615
Hydroxy-Carboxylic Acid, Decomp. of. (Cazenave)	386
Market for. (Price). (T.R.)	934
Mixtures of Acetic Acid and, Form. of Layers in. (Lime-	
harger)	300
Prep. of, from Petroleum and Residuum. (Nikoforow)	346
Purif. of. (Haller and Muehl)	766
Benzenesulphonic Acid. (Hinsberg and Himmelschein)	922
Benzenoid Amines, Researches on Tertiary. (De Breton	
Evans)	108
Benzidine and Tolidine, Valuation of. (Vaubel)	385
Benzoates, Determ. of Alkaline, by Titration. (Rebiere)	223
Benzoic Acid, Prep. of Ortho-Sulphamide. (P) Krekel	710
Sulphimide, <i>p</i> -Bromaniline Sulphonic Acid and Prep. of.	
(Kreis)	49
Benzol, Estim. of Thiophene in. (Deniers)	746
Benzonaphthol, Reactions of. (Christomanos)	619
Benzoylquinine. (Wunsch)	736
Benzylated Parafuchses. (Prud'homme)	586
Berberine, Localisation of. (Sauvan)	736
Bergamot Oil. (Schimmel and Co.)	925
Oil, Exam. of. (Borntrager)	223
Berlin, Testing Portland Cement in. (Gary)	809
Trade and Industries of, in 1895. (T.R.)	685
Bessemer Steel, Conversion of, into Cementation-Crucible	
Steel. (Kern)	811
Bessemerizing Nickel Matte. (Edwards)	96
Bettel Process, Extract of Gold from Slimes by the	813
Beverage, Prep. of, from the By-Products of Dairies. (P)	
Bernstein	608
Beverages, Detect. of Dulcine in. (Jorissen)	620
Bichromate, Recovery of, from Spent Aniline Black Liquors.	
(Beltzer)	630
Bidiphenylene Ethylene and Ethane. (Graebe and Stindt)	565
Birch Wood, Gum from. (Johnson)	605
Bismuth Bichloride. (Thomas)	556
Sulphate, Testing. (Dott)	834
Solubility of Zinc in. (Spring and Romanoff)	814
Sulphide, Solubility of, in Sodium Sulphide. (Stillman)	678
Treatment of Impure. (P) Zakorski and others	817
Bisulphite, Bleaching Wool with, by the Wet Process	906
Liquor, Separ. of Sulphur during the Boiling of Wood with.	
(Harpt)	735
Bitumen, Prep. of Solid Resins and Aromatic Hydrocarbons	
from. (Adiasiewitsch)	346
Prod. of, from Petroleum Naphtha. (Koundzy)	533
Blackboards, Liquid Comp. for. (P) Bourlez	602
Blanc Fixe, Prep. of.	918

	PAGE		PAGE
Calcium Acetate—cont.		Carburetted App: (P) Hancock and others	441
Lactate in Indigo Vats.	650	App: for Gas Generators. (P) Guldin	106
Saccharate, Treatment of, in Filter Presses.	604	Carburettors, Fittings for Water-Gas. (P) Curlier	265
Sulphide, Obtaining Hydrosulphide of Sodium from. (P)		Carcases and Offal, App: for Treating. (P) Orto	603
Willeox. From The Chem. Fab: Griessheim.	203	Carrage-M Liquid Ammonia on board Ship. (T.R.)	538
Tartrate, Solubility of. (Enell)	670	Carvacrol, Test for. (Correll)	222
Calico and Linen Printing, Use of Alizarin Blue S in.	560	Casein, Colour-Lakes prep: from. (Diebner)	538
And other Woven Fabrics, Printing. (P) Rivett and Scott	187	In Milk, Rapid Determin. of. (Deniges)	532
Bleaching, Dyeing, &c., Waste, Treatment of. (Naylor)	15	Manuf. of Ammonium Comp: of. (P) Mayet	211
Printing. (Class V.) 31, 111, 196, 271, 333, 418, 540, 589, 649,	804	Casks, &c., Removing Pitch from. (P) Blatt. From Froh-	
California, Matte Smelting in. (Lanz)	730	berg.	288
Min: Prod: of, in 1895. (T.R.)	359	Cassel-Human Bromine Process of Gold Extraction (McIlhenny)	598
Olive Oil of. (T.R.)	753	Catechin and Catechu-Tannic Acids, Dyeing Properties of.	
Physical and Chem: Properties of Oils of. (Blasdale)	245	(Hummel and Brown)	122
Prod: of Quicksilver in. (T.R.)	752	Catezu, Process and App: for Sterilising. (P) Leman	298
Treatment of Zinc-box Precip: by Cyanide Process in.		Cattle-Food, Manuf: of. (P) Friderichsen	151
(Brown)	557	Caucasian Petroleum Deposit in the Krasnodar Province of the	
Calorimeter, Use of, in Detect: Adulteration in Butter and		(Niedenthal)	345
Lard. (De Schweinitz and Emery)	560	Caustic Lyes of the Alkalis, Prod: of. (P) Murray. From The	
Camphor, Conversion of Dextro-Camphoric Acid into. (Haller)	372	Chem. Fab: Rhenania	114
Distill: from Leaves. (Hooper)	218	Cells for Batteries. See under Batteries.	
Export of, from Japan. (T.R.)	227	Celluloid, Coating with Coloured Lacquer. (Perli)	720
Levo-Fenchone, a New Isomer of. (Wallach)	470	Collodion, &c., Manuf: of, from Paper Pulp. (P) Grand-	
Manuf: of, Artif: (P) Richardson	671	jean	132
Partial Synthesis of. (Bresl and de Rosenberg)	372	Cellulose, Action of Nitric Acid on. (Knecht)	419
Prep: of Powdered. (P) Schmidt	614	Bodies, Prod: of Explosives from. (P) Theodorovic	376
Trade of China. (T.R.)	226	Comp: Manuf: of. (P) Marga	828
Camphoric Acid, Conversion of Dextro- into Camphor.		Ferment: of. (Omellianski)	129
(Haller)	372	Filter of. (Pottvin)	673
Canada, Min: Prod: of, in 1895. (T.R.)	304	Increase of Temp: of, on Absorption of Amino Moisture.	
Petroleum in. (T.R.)	752	(Beadle and Dahl)	352
Wood-Pulp Industry of. (T.R.)	57, 371	Manuf: of, for Paper Manuf: &c. (P) Dittok and Merrel	372
Caoutchouc and Gutta-Percha Substitutes.	268	Quant: Estim: of. (Lange)	137
Exports of, from Para. (T.R.)	567	Solution of, by Enzymes. (Gries)	464
Prod: of, in Brazil. (T.R.)	504	Celluloses, Constitution of the Cereals. (Cross and others)	386
Caramel Constituents of Cane-Sugar. (Volmer)	286	Cement. (Candell)	451
Carbides, Metallic. (Moissan)	797	Action of Water on. (Stutzer)	595
Metallic, for Prod: of Acetylene. (P) Willson	103	And Cement-Mortar, Manuf: of. (P) Nalmsen	109
Or Acetylides of the Earth Metals, Manuf: of. (P) Buller	265	And Concrete, Electrical Conductivity of. (St. Linckey)	725
Prod: of Metallic and Gas therefrom. (P) Ellis. From		App: for Sifting. (P) Watson and others	36
Willson	166	Comp: of a New. (P) Clerly	452
Carbinol, Formula of Triphenyl. (Frey)	122	Concrete, Manuf: of. (P) Bird and Wright	452
Carbohydrates, Action of Alkalis on. (Lohy de Brign and		Effect of Kentish Ragstone on Portland. (Butler)	809
van Ehenstein)	210	Estim: of Lime in Raw Portland. (Klage)	559
Fermentable. (Prior)	915	For Binding Light Substances. (P) Haifer	452
Of the Sugar Cane. (Prinsen-Geerlings)	730	For Metals, Experiments with. (Raboff)	114
Carbolic Acid, Formula of Anthracene, in the Distill: of. (Kohler)	107	German. (T.R.)	113
Carbon and Aluminium Alloys, Analysis of. (Moissan)	136	Hardening of Portland, in Sea Water. (Bech)	348
Bisulphide, Manuf: of, and App: therefor. (P) Holt and		Hot Tests for. (Erdmenger)	380
Millard	594	Inf: of Magnesia on Strength of. (Haas and McGraw)	809
Bisulphide, Manuf: of Sulphocyanides from. (P) Goerlich		In Germany, Slag. (Mason)	275
and Wichmann	357	Kilns for Burning. (P) Foster	904
Combustion of, in Air. (Naumann)	439	Manuf: of. (P) Chesborough	452
Conditions which cause Crystalline Low. (Düppel)	654	Manuf: of. (P) Stark	452
Cylinders for Electrolytic Work, Porous. (Lohy)	207	Manuf: of Portland, in Belgium	809
Dioxide, Collee: and Util: of. (Kerr-Thomas)	129	Manuf: of Portland and other. (P) Harry and Seaman	109
Dioxide, Exam: of Liquid. (Schwalbe)	559	Manuf: of Waterproof Elastic. (P) Caten	545
Dioxide, Prod: of, during Decomp: of Sugar. (Bertliet		Mortar, Inf: of Charac: of Sand on. (Chopier)	129
and Andre)	821	Or Plaster Comp: Manuf: of. (P) G. By. From Schneisser	350
Dioxide, Solidifying. (P) Elworthy and Henderson	274	Or Varnish, Waterproof. (P) Pullen	729
Dioxide Test for Quinine Sulphate. (Kuhli)	681	Pigments, &c., Manuf: of Finely Pulverised Substances for	
Escape of Unconsumed, from Coal-Gas Flames. (Wright)	24	Prod: of. (P) Patrick	653
Inf: of, on Iron. (Arnold)	453	Prod: of New. (P) Robbins	810
In Al Alloys, Analysis of Total. (Gauthere)	830	Sand. (Wallen)	358
In Zinc. (Funk)	209	Testing. (Berger)	380
Manuf: of, for Electrical Purposes. (P) Shewsbury and		Testing in Berlin, Portland. (Gory)	809
others.	25	Trade of Berlin. (T.R.)	685
-Monoxide and Coal-Dust, Action of, in Causing Colliery		Cements. (Class IX.) 36, 114, 199, 275, 38, 451, 545, 595, 653, 720,	
Explosions. (Orsman)	319	809, 904	
Note on "the Missing." (Hogz)	721	Clays, &c., Continuous Kilns for. (P) Vazghan	810
Prod: of Metals and Alloys containing. (P) Kaufmann	129	Manuf: of, for Prod: of Artif: Stone. (P) Weiswarth and	
Rate of Diffusion of, in Iron. (Roberts-Austen)	151	Hoeft	36
Rendering Gases Rich in, suitable for Lighting Purposes.		Manuf: of Slag. (P) Jorgensen	358
(P) Buller	265	Ceramic Clays of the South. (Lanz)	36
Solubility of, in Iridium, Rhodium, and Palladium.		Cereals, Estim: of Starch in. (Effront)	323
(Moissan)	622	Estim: of Starch in. (Lindet)	924
Sugars Richer in, from Galactose. (Fischer)	56	Cerium, Separ: of, from Lanthanum and Europium. (Dross-	
Tetrachloride as a Substitute for Petroleum Spirit	588	bach)	889
Transformation of, into Plumbago. (Reyval)	38	Separ: of Thorium and. (Preseus and Hamza)	702
Carbonado (Black Diamond), Specimen of, from Brazil.		And Zirconium Oxides. (Barnes)	429
(Moissan)	141	Cerotic and Melissic Acids-existing Free in Beeswax, Properties	
Carbonic Acid Gas, Collee: and Use of. (P) Boul. From the		of. (Marie)	362
Pabst Brewing Co.	552	Ceylon, Para Rubber in. (T.R.)	567
Acid Gas, Manuf: of. (P) Elworthy and Henderson	719	Change of Address. See under Address.	
Acid, Increasing Stability of Liquids containing. (P)		Charas, the Resin of Indian Hemp. (Ward and others)	572
Gronwald	733	Charcoal, Methyl Alcohol and Acetic Acid, Quant: yielded by	
Acid, Manuf: and Uses of, in Germany.	650	Different Woods. (Barillon)	316, 584
Acid, obtaining, from Gas Mixtures. (P) Raydt	594	Prod: of Peat. (P) Rose	643
Acid, Rapid Determin: of, in Air. (Henriet)	617	Pure of Sugar Solutions by Animal. (P) Kastenreue	823
Acid, Separ: of, from Prod: of Combustion. (P) Elworthy		Cheese, Chem: Investigation of. (Stutzer)	746
and Henderson	265	Extrac: of Fat for Exam: (Henzold)	386
Anhydride in Air, Pettenkofer's Method for Determin:		Chemical Imports of the United States. (T.R.)	58
(Lettis and Blake)	421	Industry in Alicante. (T.R.)	143
Anhydride, Modif: of Schrotter's App: for Determin: of.		Industry in Germany. (T.R.)	483, 629, 897
(Kohn)	248	Trade of Japan. (T.R.)	144
Oxide and Carbon Dioxide, Safeguards against.	825	Trade of Turkey in Asia. (T.R.)	931
Oxide, Detect: and Estim: of, in the Air. (Clowes)	742		
Oxide, Escape of, from Coal-Gas Flames. (Wright)	24		
Oxide, Poisoning by. (Herman)	854

Col. Mat. and Dyes, Various— <i>cont.</i>		Composition— <i>cont.</i>	
Manuf. of Substantive Cotton Blue. (P) Inray. From The Farb. vorm: Meister, Lucius, and Bruning	269	For Coating Boilers, Non-corrosive. (P) Lowe	261
Prod. of Violet and Blue Azo. (P) Newton. From The Farb. vorm: F. Bayer and Co.	415	For Inking Rollers, &c. (P) Murray and Speirs	311
Manuf. of Yellow, Brown, and Black. (P) Newton. From The Farb. vorm: Bayer	896	For Manuf. of Building Materials. (P) Wilkinson	720
Quinazine and Oxazine. (Mohlan und Uhlmann)	385	For Polishing Metal. (P) Rayner	37
Rendering, Soluble. (P) Soc. des Matieres Colorantes and R. Vidal	30	For Prep. Materials for Photo-Prints. (P) Seidenfelder and Kehle	357
Solvents for Induline. (Gassmann)	584	For Preserving Ships' Bottoms, Wool, &c. (P) Gunn	662
Triphenylmethane. (Sandmeyer)	706	For Preventing Moisture on Walls. (P) Ludewig	339
Fisetin, Constitution of. (von Kostanecki and Tambor)	191	For Purifying Water. (P) Lachery	289
Fluorindines, Constitution of the III. (Kehrmann and Burgin)	536	For Removing Paint. (P) Thompson. From Bailey	363
Fuchsin and Amino-carbimols, Reactions of. (Rosenstiehl)	555	For Repairing Leaks in Pneumatic Tyres. (P) Howe and Langley	518
Fuchsin, Benzylated para. (Prud'homme)	586	For Treating Diseases of the Vine, &c. (P) Johnson. From Lasimolles and Fréchet	48
Fuchsin, Properties of, and Oxidation by Lead Peroxide. (Prud'homme)	535	For Use in the Plastic Arts. (P) Rawdon and others	450
Hydrols and Aromatic Amines, Condensation of. (Prud'homme)	585	Compound for Use in Connection with Paints. (P) Sellars	207
Hydroxyanthraquinones, Manuf. of Derivatives of. (P) Newton. From The Farb. vorm: Bayer and Co.	191	App. for Treating Bituminous. (P) Badgley and others	102
Indigo, Formula: of, by Action of Sunlight. (Engler and Dorant)	191	Concent. App. (P) Moore	43
Indigo-Red and Indigo-Red Sulphonic Acid. (Fasal)	348	App. (P) Wilson	541
Indigotin, Red Isomeric of. (Schunck and Marchlewski)	193	Concrete, Electrical Conductivity of. (St. Lindeek)	725
Indulines, Relation of, to the Safranines. (Kehrmann)	536	Condenser for Distilling Small Quant. of Substances. (Eberhard)	294
Indulines, Relations of, to Safranines. (Fischer and Hepp)	192	New Form of. (Walther)	673
Iodo Derivatives of Anisol. (Reverdin)	534	Convicine, Alloxantin obtained on the Hydrolysis of. (Ritt- hausen)	469
Isatin, Derivatives of. (Schunck and Marchlewski)	193	Reactions of Alloxantin from. (Ritthausen)	715
Meldola's Base, Prep. of. (Paul)	707	Cooling App. (P) Hart	450
Metantramline, Alkaline Reduction of. (Meldola and Andrews)	28	App. for Fluids. (P) Klein	261
Naphthalenesulphonic Acid, Prod. of. (P) Newton. From The Farb. vorm: F. Bayer and Co.	110	App. for Liquids. (P) Krack	527
Naphthalene Derivatives, Isomeric III. (Friedlander and Rüd)	331	App. for Liquids. (P) Ramsden and Southby	700
Naphthazarin from 2-Tetranitronaphthalene, Formula: of. (Will)	192	See also under Heating App.	
Nitranilines, Prep. of the Three. (Brauns)	192	Copper, Action of Hydrochloric Acid on. (Engel)	117
Nitrotetramethylamidotriphenylmethanes, Reduction of. (Prud'homme)	268	Alloys, Mech. Properties of. (Charpy)	117
Nitrotoluene, Treatment of Technical. (P) Green and Benley	709	Analysis of Crude. (Jean)	677
Ortho-amidodiphenylamine, Oxidation Prod. of. (Fischer and Dischinger)	536	And Concent. Sulphuric Acid. Reactions between. (Baskerville)	201
Oxazines. (Mohlan und Uhlmann)	585	And other Metal Sheets, Electrical Manuf. of. (P) Cowper-Coles Syndicate and Cowper-Coles	281
Oxazones. (Mohlan und Uhlmann)	585	And Zinc Alloys, Structure and Constitution of. (Charpy)	455, 455
Para-amido-benzyl Alcohol, Prod. of. (P) Johnson. From Kalle and Co.	20	Cyanide Method of Determining. (Flynn)	677
Paranitro Comp. Electrolytic Reduction of. (Noyes and Dorrance)	191	Determ. of Oxygen in Commercial. (Boult)	296
Paranitrodiazobenzene Red. (Fab. de Prod. Chim. de Thann et de Mulhouse)	27	Direct Method of Smelting. (James)	811
Phenazine, Formula: of. (Fischer)	616	Electro-Deposition of Iron on. (P) Morris	362
Phthalens, Manuf. of. (Fischer and Co.)	586	Electrolytic Prod. of Metallic. (P) Burghardt and Riez	816
Purpurinesulphonic Acid and Purpurine, Manuf. of. (P) Inray. From The Farb. vorm: Meister, Lucius, and Bruning	416	Estim. of in Tin Dross. (Rurup)	560
Pyrocatechin-anhydro-monoacetic Acid, Manuf. of. (P) Chem. Fab. von Heyden	588	Estim. of Sulphur in Refined. (Heath)	218
Quercetin in Outer Skins of Bulb of the Onion. (Perkin and Hummel)	616	Extrac. of from Sulphuretted Ores. (P) James	724
Safranines, Const. of. (Fischer)	616	Freezing Point Curves of Binary Alloys containing. (Heycock and Neville)	810
Sulphonic Acids derived from Naphthalene. (P) Abel. From The Actien Ges. für Anilin Fab.	270	In Alloys, Analysis of. (Gauthier)	830
Tetrazo Comp. Manuf. of Coupled. (P) Inray. From The Soc. of Chem. Ind. in Basle	30	Ingot, Solutions for Use in Casting. (P) Lunt	120
Thiodiphenylamine. (Unger and Hoffmann)	331	In Iron and Steel. (Raymond)	811
Toluene-azo-Cresols, Reduction of. (Heber and others)	27	Melting Point of. (Holman and others)	655
Toluene-azo-Phenols, Reduction of Ethers of. (Dusterbehn and others)	27	Method of Estim. Sugar. (Kahman)	561
Trisorescinol. (Hesse)	581	Nickel Alloys. (Gautier)	598
Colours, Alkaline Discharge on Turkey-Red. (Maslowski)	355	Obtaining from Ores. (P) Burghardt	1907
And Mordants, Thickeners or Vehicles for. (P) Horn. From Maybury	32	Occurrence of in Vegetables. (Vedrodi)	552
Extrac. of, by Volatile Solvents. (P) Meiz.	792	Occurrence of in Wine. (Karsten)	367
Exam. of, and their Appearance under Illuminants. (Baker)	894	Pyrites, Comp. and Constitution of. (Schneider)	275
On Cotton, Fading of. (Ogloblin)	32	Quant. Analysis of. (Heidenreich)	744
On Wool, Fastness of, to Light and to Street-Mud. (Dommergue)	271	Quant. Estim. and Separ. of. (Mawrow and Muthmann)	381
Prod. Patterns in Cotton Fabrics. (P) Michel	712	Report on the Extrac. of. (Schmabel)	651
Report on Action of Light on Dyed. (Thorpe and others)	798	Residues, Separ. of Tellurium from. (Whitehead)	202
With Silk-like Gloss, Prod. of, on Fibres, &c. (P) Heberlein	650	Separ. of, from Zinc and Cadmium. (Heidenreich)	744
Colza Seeds, Adulteration of. (Pajot)	490	Separ. of Silver from. (Heidenreich)	744
Combustion of Coal and Gas in House Fires. (Cohen and Russell)	86	Tensils, Comp. Metal Sheets for. (P) Inray and Martin	658
Of Lighting Gas in Gas Engines. (Haber and Weber)	888	Coppers, Impts. in. (P) Wood	261
Of Oils Spread on Cotton Wool, Liability to Spontaneous. (Mackey)	30	Cops, App. for Dyeing, Bleaching, &c. (P) Hepworth-Collins	805
Conestible, Prep. Fats for Use as. (P) Gray, jun.	131	Corallin and Magenta, Chem. of. (Zalkowski)	27
Commercial Treaties of Germany, Effect of. (T.R.)	623	Cerouilla and Coronillin. (Schlagdenhauffen and Reeb)	737
Committee of Congress on Alcohol in the Manuf. and Arts. (T.R.)	929	Coronillin. (Schlagdenhauffen and Reeb)	737
Composition as Substitute for Whalebone. (P) Kuhlmann and Baier	462	Corsica, Mines in. (T.R.)	933
For Blackboards. (P) Boulez	602	Corybulline. (Ziegenbein)	826
For Cleansing Polished Wood Surfaces. (P) Postlethwaite	818	Corycaine. (Ziegenbein)	826
		Corydaline. (Ziegenbein)	825
		Corydalis Alkaloids. (Schmidt)	826
		Cava, Alkaloids of. (Ziegenbein)	825
		Cotton, Characterisation of. (Formanek)	53
		Cotton. (Class V.)	30, 111, 196, 271, 352, 448, 539, 588, 648, 803, 898
		Albumin as a Fixing Agent for Pigments on. (Flintoff)	253
		And other Fibres, App. for Scouring, Bleaching, &c. (P) Hepworth-Collins	592
		And Wool, App. for Dyeing Loose	801
		"Animalising." (Knecht)	419
		Bleaching. (P) Endler	191
		Bleaching Electrolytically. (Wartner)	900
		Cloths, Prod. of Coloured Borders on. (P) Sharp	901
		Fabrics, Printing. (P) Rivett and Scott	197
		Fading of Col. on. (Ogloblin)	32
		For Use in Manuf. of Gun cotton, Inspection of. (Munro)	214
		Prod. of Silk-like Gloss on. (Laurie)	898
		Warps, Alsatian Method of Sizing and Dressing. (Acker-mann)	589
		Waste, Cleaning and Degreasing. (P) Mitchell	898
		Waste, Degreasing and Cleansing. (P) Turney	589
		Yarn, p-Nitramine Red on. (Romer)	901
		Zinc Lactate as Mordant for. (P) Boehringer and Sohn	801

Crystals, Prep. in Refineries. (P) Drost	912	Diastatic Power of Malt, Determin. of. (Ling)	621
"Cuban" (Copper Pyrites), Comp. of. (Schneider)	275	Power in Malt, Estim. of. (Sykes and Mitchell)	621
Cupric Oxide Reducing Power of Dextrose. (O'Sullivan and Stern)	913	Diazo Comp. Apphe. of Double Salts of, with Zinc Chloride. (Smirnoff and Rosenthal)	901
Cuprous Comp., Detect. of Nitrites by. (Sabatier)	616	Diazomethanedisulphonic Acid, Prep. of. (Pechmann and Manek)	301
Curarine, Localisation of. (Sauvan)	736	Dibromo-Gallie Acid and its Derivatives, Action of Nitroso-dimethylaniline on. (Bietrix)	538
Customs Decisions in United States. (T.R.)	481	Dibromozallie Acid, Brown Col. Malt: obtained from. (Bietrix)	348
Decisions in United States. (T.R.)	927	Dictionary of Inorg. Chem. Solubilities. (Coney)	566
Duties Repeat Act, 1896, in Western Australia. (T.R.)	927	Digitoxin. (Kiliani)	737
Regulations. 57, 143, 225, 302, 388, 481, 623, 719, 836, 927	225	Dihydroxynaphthalene, Prod. of New. (P) Newton, From The Parb. form: Bayer and Co.	110
Reg. affecting the Port of St. Nazaire. (T.R.)	225	Diodomethyl Salicylate. (Arnheim)	469
Reg. of Austria-Hungary. (T.R.)	226	Dimethylaniline Derivatives. (De Bereton Evans)	108
Tariff of Brazil, Revision of. (T.R.)	143	Derivatives. (Schuster and Pinnow)	534
Tariff of Guatemala. (T.R.)	303	Dimethyl- <i>m</i> -Amidophenol, Reactions of. (Leleuvre)	584
Tariff of New Zealand. (T.R.)	37, 143	Dinas Bricks. (Seger and Cramer)	451
Tariff of Victoria, New. (T.R.)	927	Dinitronaphthalene-1:8. (Gassmann)	534
Cutch, Treatment of Mangrove Bark to obtain. (P) Clarke	588	Dinner, The Annual	526
Cyanide Method of Determin. of Copper. (Flynn)	677	Disinfectant and Purif. Comp. (P) Burton	607
Process, Applied to Concent. from Nova Scotia Gold Ore. (Lodge)	457	Chlorine as a. (Clayton)	329
Process, Chem. of. (Wells)	116	For Sheep Dipping. (P) Passmore and others	607
Process for Extrac. of Gold in the United States	812	Formaldehyde as a. (Schepilewsky)	734
Process for Treatment of Gold, Chem. of. (Schneider)	57	Formic Aldehyde as. (Puhl)	917
Process in the United States. (Packard)	813	Manuf. of Antiseptic. (P) Boul. From Fritzsche and Co.	917
Process Treating Ores by the. (P) Appleby, From Gowans	599	Prod. of. (P) Hiscott	48, 917
Process, Treatment of Zinc-box Precip. in. (Brown)	457	Prod. of a. (P) Wade	48
Solutions, Extrac. Gold and Silver from, by Electricity. (P) Pflieger	601	Disinfectants. (Class XVIII.)	48, 132, 212, 286, 369, 467, 553, 609, 667, 731, 825, 917
Works, Gold Extrac. in. (Caldecott)	457	(P) McArthur	212
Cyanides and Ferrocyanides, Manuf. of. (P) Raschen and Brock	513, 513	For Manure, Manuf. of. (P) Tralls and Burmeister	125
And Ferrocyanides, Manuf. of Alkaline. (P) Downing, From Moise	903	Manuf. of. (P) Whitaker	825
Experiments relating to the Manuf. of. (Courroy)	8	<i>See also under Antiseptics.</i>	
Extrac. of, from Gases. (P) Livesey	614	Disinfecting App. (P) Defries. From Herscher and Co.	369
Manuf. of. (P) Crowther and others	357	By Formaldehyde. (P) Soc. Anon. de l'Institut R. Pictet	608
Manuf. of. (P) Pflieger	594	Disinfection, Formaldehyde Lamp for. (Tollens)	290
Manuf. of. (P) Swan and Kendall	273	Method of. (P) Sjostrom	553
Manuf. of. (P) Thompson, From Finlay and Derry	274	Distill. App. (P) Yagn and Bessonoff	23
Manuf. of, from Sulphocyanides. (P) Raschen and Brock	807	App. for Tarry Mat. (P) Dvorkovitz	706
Manuf. of Metallic. (P) Kellner	274	Distill. Columns, Clearing Overflow Pipes of. (P) Hirzel	641
Manuf. out of Molasses. (P) Reichardt and Bueh	114	(Destructive), Tar Products, &c. (Class III.)	23, 106, 191, 267, 345, 443, 533, 583, 645, 706, 797, 893
Obtaining, from Gases. (P) Foulis and Holmes	114	Recovering By-Products from. (P) Merriek and Washburn	262
Prod. of. (P) Twynam	357	Tube for Nitrogen Determin. (Hopkins)	616
Prod. of Metallic. (P) Willson	808	Disulphonic Acid, Deep Blue Nitro-. (Sabatier)	622
Wet Methods of Manuf. (Caro)	34	Dithiazole Derivatives. (Lauth)	348
Cyanogen Comp., Prod. of. (P) Frank and Caro	544	"Draft" or Spent Grains, Util. of. (P) Bailey and Ford	607
Comp., Prod. of. (P) Morgans	198	Drains and Sewers, Purif. the Air of. (P) Reeves	607
Comp., Prod. of. (P) von Rad and Rosenfels	357	Driers, Properties of. (Weger)	728
Forma. of, from Ammonia. (Beremann)	449	Dringys granatensis, L., Bark and Leaves of. (Hesse)	49
From Ammonia	543	Dross, Estim. of Tin and Copper in Tin. (Kurup)	569
Cyclopentadiene in Coal Tar, the Indene of the Fatty Series. (Kraemer and Spilker)	443	Drown's Method of Determin. Sulphur in Pig Iron. (Auchly)	381
Cylinders for Compressed Gases, Report of Committee. (T.R.)	228	Drug Imports of the United States. (T.R.)	144
Cynoetionine, Researches on. (Rosendahl)	757	Trade in Russia. (T.R.)	754
		Trade of Berlin. (T.R.)	685
		Trade of New South Wales. (T.R.)	933
		Drugs and Chem., Japanese Trade in. (T.R.)	144
		Mill for Grinding, &c. (P) Schutte	262
		Mydriatic. (Lauterer)	212
		Drying App. (P) Cummer	341
		App. (P) Heys. From Hundhausen	887
		App. (P) Kropff	358
		App. (P) Ludwig, From Moser	439
		App. (P) Makin	567
		App. (P) Zimmermann and others	101
		App. for Fibrous Materials. (P) Theisen	579
		And Absorbing App. (P) Saatzmann	641
		Semi-Fluids. (P) Heys, Hundhausen	887
		<i>See also under Condensing, Heating, and Evap.</i>	
		Dulcine, Detect. of, in Beverages. (Jorissen)	620
		Dulong's Method for Calculation of Caloric Value of Coal. (Arth)	794
		Durene-carboxylic Acids. (Meyer and Wohler)	894
		Dust and Fume, Methods of Collec. Metallurgic. (Hes)	209
		Efficiency of Corrosive Sublimite, as a Germicide. (Chavigny)	734
		Duties on British Imports in Japan. (T.R.)	226

Electro-Depositing of. (P) Elmore, From Elmore	817	Resources of Newfoundland. (T.R.)	931
Electro-Deposition of. (Rosing)	562	Statistics of the United Kingdom for 1895. (T.R.)	750
Electrolytic Deposition of. (P) Raleigh	600	Min. in Southern Russia. (T.R.)	227
Electrolytic Separ. and Refining of. (Tommasi)	600	Mines in Corsica. (T.R.)	933
Estim. of Antimony in. (Clark)	255	Mining Industry of Dutch East Indies. (T.R.)	143
Experiments with Cement for. (Rudeloff)	114	In Japan. (T.R.)	887
Extrac. of, from Galena, &c. (P) Fry and others	546	Statistics of France. (T.R.)	113
Extrac. of, from Ores. (P) Miles	202	Mixing App. for Accelerating Chem. Reactions. (Markovnikov)	172
Extrac. of, from Refractory Ores. (P) Woolford	724	App. for Liquids. (P) Brotherton and Holmes	641
Extrac. of, from their Ores. (P) Lewis and Gelstharp	814	Mohr's Electrolytic Method for Refining Silver. (Faunce)	361
Furnaces for Smelting. (P) Roussau	203	Mohamba Seeds, Comp. of. (Hobert)	660
In Liquids, Estim. of Minute Quant. of. (Budden and Hardy)	247	Moisture, Comp. for Prev. on Walls. (P) Ludewig	359
Manuf. of Alloys of Refractory, with more Fusible Metals. (P) Thompson, From La Soc. Neo Metallurgie Marbenn, Chaplet, and Co.	203	Extrac. from Pent. (P) Rose	641
Manuf. of Carbides or Acetylides of the Earthy. (P) Bullier	265	In Aniline, Ortho- and Paratoluidine, Estim. of. (Dobriner and Schranz)	208
Obtaining Precious, from Solutions. (P) MacArthur	724	In Wood Pulp. (Sundall)	230
Of Different Melting Points, separ. (P) Langen	546	"Mokume," a Japanese Alloy.....	116
Of the Alkaline Earths, Fixation of Nitrogen by. (Maquenne)	225	Molasses, Determ. of, in Honey. (Beckmann)	622
Or Alloys, Obtaining, by Electrolysis. (P) Jordis	459	Electrolysis of Spent.....	403
Ornamenting and Printing on. (P) Thacker	284	Extrac. of Sugar from. (Langen)	822
Precip. of Precious, from their Solutions. (P) Sulman	119	Manuf. of Cyanides from. (P) Reichardt and Buch	111
Prod. and Decomp. Comp. of. (P) Blackmore	658	Pulp, Prep. (P) Kastengren	664
Prod. of Double Aluminum Sulphides with Alkaline. (P) Peniakoff	599	Purif. of. (P) Kastengren	823
Prod. of Nitrides of, from Atmos. Nitrogen. (Rossel and Franck)	273	Purif. of, by Animal Charcoal. (P) Kastengren	125
Protect. from Rust. (P) Newton, From The Farb. vorm. Bayer	208	Recovery of Sugar from. (Kassner)	913
Reducing Metallic Oxides by Amalgams of Alkaline. (P) Mond	547	Syrup, &c., Purif. of. (P) Cassel and Kempe	272
Soldering and Brazing. (P) Ellis	815	Molashkin and Buckskin, Manuf. of Printed. (Maslowski)	714
Solution and Diffusion of, in Mercury. (Humphreys)	199	Molybdenum, Analysis of. (Heidenreich)	705
Structure of. (Osmond and Roberts-Austen)	810	Bronzes. (Stavenhagen and Engels)	205
Treating Slimes from Ores of Precious. (P) Crawford, From Keck	546	Estim. of. (Friedheim and Euler)	220
Varnish for Protec. Bright. (P) Crowther	49	Prep. and Properties of Pure. (Moissan)	723
Metanitraniline, Alkaline Reduction of. (Meldola and Andrews)	28	Trioxide and Vanadium Pentoxide, Estim. of, in Presence of each other. (Friedheim and Euler)	220
-Nitraniline-sulpho Acid and its Analogues, Manuf. of. (P) Imray, From The Farb. vorm. Meister, Lucius, and Bruning	539	Molybdic Acid as a Reagent for Alcohol. (Merck)	297
-Nitraniline-sulpho Acid, Manuf. of. (Imray, From The Farb. vorm. Meister, Lucius, and Bruning)	539	Solution as a Reagent. (Meillere)	378
Methane and Hydrogen, Determ. of, by Explosion. (Gill and Hunt)	295	Monazite, Chem. of Constituents of. (Drossbach)	889
Methyl Alcohol Process of Separ. Boric Acid Simplified. (Jay and Dupasquier)	136	In Germany. (T.R.)	626
Alcohol, Yield of, from Different Woods. (Barillot)	545, 584	Sand, Analysis of, and Estim. of Thorium. (Glaser)	675
Methylamines, separ. of. (Delépine)	613, 620	The Market for. (T.R.)	627
Methylated Spirit, Report on, for Year ending March 31, 1896. (T.R.)	685	Mond Producer-Gas applied to the Manuf. of Steel. (Darby)	529
Spirits. (T.R.)	930	Mordants, Fixing Metallic, on Fibres. (P) Ashworth	901
Spirit, Carriage of. (T.R.)	838	Morin. (Part I.) (Bablich and Perkin)	445
Methylation of Spirits. (T.R.)	929	Morocco Fusion Process, The	545
Methylene Blue, Distribution of, between Water and Mercersell Cellulose. (von Georgievics and Lowy)	31	Morphine, Determ. of, in Opium. (Loof)	834
Methylenedibutanic Acids, Prod. of, for Use as Disinfectants. (P) Dürkopp	917	Estim. of, in Opium. (Looff)	478
Methyleugenol, Synthesis of. (Moureu)	133	Reaction in Estim. of Alkaloids. (Kippenberger)	748
Methyl Nitrate, Prep. of. (Delépine)	133	Mortar Analysis, Measure Process of. (Patchett)	474
		Analysis of. (Dibdin and Grimwood)	675
		Analysis, Prep. Process of. (Patchett)	474
		Process for Manuf. of Cement. (P) Nahnsen	149
		Prod. of Quick-setting, of Hydraulic Gypsum. (P) Mack	720
		Strength of Common. (Beschetzniek)	36
		Mortars. Class IX.) 36, 114, 199, 275, 358, 451, 545, 593, 653, 720, 809, 904	
		Motor Engines, App. for Rendering Furnace Gases suitable for (P) Thwaite and Gardner	724
		Moulds which partake of the Nature of Yeasts and Moulds. (Jorgensen)	604
		Mucilage separated in the Osmose Process. (Anderlik)	286

Perfumes, Manuf. of. (P) Ekenberg and Montén	373	Phenylene and Tolylen-Oxamic Acid, Manuf. of Col. Mat. with. (P) Murray. From Remy	709
Manuf. of. (P) Otto and Verley	874	Philippines, Pharmaceutical Products in the. (T.R.)	303
Manuf. of New. (P) Chem. Fab. von Heyden	614, 742	Phloroglucinol for Determ. Wood Pulp in Paper. (Tollens) ..	833
Persulphates, Analysis of. (Ulzer)	235	Test for Determ. of Pentoses. (Tollens)	744
Persulphuric Acid, Forma. of. (Ellis and Schonherr)	360	Phosphate Discoveries in Tennessee. (T.R.)	837
Acid, Forma. of, in Storage Cells. (Schoop)	360	Dispute in Algeria. (T.R.)	628
Acid in Lead Accumulators. (Ellis and Schonherr)	277	Estim. of Nickel and Zinc as. (Clark)	866
Perth, Opening of New Laboratories at	846	Ground Min. as a Fertiliser. (Shutt)	602
Petit Grain, Oil of. (Duyk)	919	Manganous Ammonium, A New Manure	550
Petroleum, Acid Test for	678	Properties of Ferric. (Caven)	17, 170
And Bitumen, Prep. of Solid Resins and Aromatic Hydrocarbons from. (Adiaslewitsch)	316	Phosphates and Caustic Alkali, Manuf. of. (P) Thompson. From The Chemische Werke vorm. Albert	903
And Ozokerite Fields in Russia, New. (T.R.)	932	Determ. of Alumina and Oxide of Iron in. (Thomson)	868
And Residuum, Prep. of Benzene from. (Nikoforow)	346	Determ. of Alumina in. (Lasne)	381
App. for Gasifying. (P) Young. From Aschner	443	Determ. of Fluorine in. (Braun)	474
Artif. Prod. of Asphalt from. (Mabery and Byerley)	267	Of America in 1895. (Peacock)	99
As Fuel for Boilers. (Le Chatelier)	702	Of Ammonia and Potash, Manuf. of. (Jamieson)	819
Benzene and Coal Tar Benzene, Distinguishing between ..	53	Treatment of Min. for Fertilisers. (P) Silcock	730
Burning Furnace. (P) Chamberlain and Beebe	704	Phosphor-Bronze, Estim. of Phosphorus in. (Oettell)	296
Capacity of, for Absorbing Atmos. Constituents. (Ostrejko) ..	26	Phosphoric Acid, Estim. of "Available" in Basic Slag. (Hoffmeister)	474
Consumption in Germany	888	Acid, Estim. of, by Titration. (De Molinari)	216
Deposit in the Kouban Province of the Caucasus. (Niedenfuh) ..	345	Acid, Estim. of, in Medicinal Wines. (Glaser and Muhle) ..	716
Determ. of Sulphur in. (Aufrecht)	680	Acid, Estim. of Manganese in. (Viard)	677
Effect of Sunlight on, and its Capacity for Absorbing Air. (Ostrejko)	345	Acid, Estim. of Soluble, in Ground Thomas Slag. (Mach and Passon)	296
Elementary Comp. of. (Engler and Jezioranski)	191	Acid in Barley and Malt. (Fernbach)	621
Esters from the Spent Acids. (Fuchs and Schill)	56	Acid in Bone Meal. (Braun)	550
Estim. Sulphur in. (Kissling)	384	Acid in Fertilisers. (Veitch)	381
Estim. of Paraffin in, by Zaloziecki's Method. (Charitschkow) ..	680	Acid in Mixed Fertilisers. "Insoluble." (Bryant)	678
Estim. of the Content of Burning Oil by the Distill. Test. (Zaloziecki)	679	And Arsenic Acids, Estim. of. (Christensen)	474
Flashing Points of. (Kast and Rose)	341	Iron Ores in the Blast Furnace, Effect of Additions of Titanif. Ores to. (Rossi)	545
Formation of. (Heusler)	584	Phosphorus, Estim. of, in Phosphor-Bronze. (Oettell)	296
Furnaces for Burning. (P) Boulton. From Dusaule	643	In Iron Ores, Insoluble. (Meyer)	743
Galician, in Germany. (Kuhlou)	345	In Steels, Inf. of Heat and Carbon on Solubility of. (Campbell and Babcock)	905
In Canada. (T.R.)	752	Prod. of. (P) Hilbert and Frank	921
In Oran. (Evrard)	706	Prod. of Pig Iron containing little. (Tholander)	359
In the Island of Tschelaken. (Charitschkoff)	583	Rendering Amorphous, a Substitute for Yellow. (P) Abel and Murray. From Bals and Grovits	471
Increasing Lighting Power of. (P) Baron	191	Spectrum of, in Fused Salts, &c. (De Gramont)	616
Industry of the District of Ter. (Tumsky)	533	Photographic Developer, Formalehyde in. (Helleim)	828
Industry, Importance of Uniform Methods of Testing. (Gans)	138	Developers, Occurrence of Luminescence in Use of. (Helleim)	835
Inf. of Resinous Constituents on the Illuminating Power of. (Charitschkow)	24	Developing Solutions. (P) Hauff	672
Investigations on American. (Mabery and Dunn)	533	Engraving, Prod. of Negatives for. (P) Bryan	50
Italian. (Flaunet)	443	Films, Separ. of Gelatin Coatings from Paper Supports in Manuf. of. (P) Wellington	471
Kerosene from Ohio. (Kissling)	25	Materials and Processes. (Class XXI.) .. 50, 214, 293, 375, 471, 557, 614, 671, 741, 828, 920	
Lamps, Comp. of the Gaseous Mixture formed in. (Kast and Rose)	341	Plates, Action of Zinc on. (Colson)	615
Lands of Germany. (Lang)	26	Printing Paper. (P) Hrdiczka-Ciszar	375
Manuf. of Gas from. (P) Foulis	613	Printing Paper. (P) Koppmann	828
Manuf. of Solidified. (P) Ekenberg	594	Prints Chem. Comp. for. (P) Schoenfelder and Keale ..	557
Naphtha, Prod. of Bitumen and Tar from. (Kouindly) ..	833	Process, Improved. (P) Mulls. From Lumiere	214
Of America in 1895. (T.R.)	687	Plates and Films, Manuf. of. (P) Oakley	214
Of Salt Creek, Wyoming. (Knight and Slosson)	583	Photographs, App. for Prod. of Coloured. (P) Edwards	293
Prod. Action of, on Aluminium. (Charitschkow)	443	In Relief, in Gold, Silver, &c. (P) Hill and Burratt	741
Prod. Inf. of Sunlight and Air on. (Ostrejko)	26, 645		
Raising the Flashing Point of, e. Improved Lamps	702		
Residues used in Bakeries. (Dunbar)	368		
Separ. of, from Water and Tar. (Ostrejko)	26		
Spirit, Carbon Tetrachloride as a Substitute for	588		
Sulphur in. (Engler)	383

Prod: of Caustic, from Soap Lyes. (P) Glatz and Luzo.....	661	Sterilising Milk and other Liquids by. (P) Pfeiff.....	609
Prod: of, in United States. (T.R.).....	58	Stearoptene, in Otto of Roses. (Urney).....	924
Use of, in the Manuf. of Cane Sugar. (Kruzer).....	913	Steel Analysis, Standard Methods of. (von Jonstorff).....	559
Sodium and Aluminium Alloys, Analysis of. (Moissan).....	136	And Malleable Iron, Annealing Articles of. (P) Frenzkow.....	659
Chlorate, Manuf. of. (P) Hargreaves and Bird.....	113	Comp: of, for Tram-Rails.....	811
Chloride, Treatment of, to obtain Bleach. (P) Backwell.....	652	Conversion of Siemens or Bessemer Steel into Cementation Crucible. (Kern).....	811
Comparative Affinities of Salts of Ammonium and. (Watson Smith).....	3	Converting Pig Iron into Malleable Iron or. (P) Sherck and others.....	815
Cyanide, Manuf. of. (P) Kellner.....	274	Copper in Iron and. (Raymond).....	811
Cyanide, Manuf. of. (P) Mackey and Hutcheson.....	593	Determ: of Carbonaceous Value of. (P) Peipers.....	52
Hydrosulphide, (P) Wilcox. From The Chem: Fab: Griesheim.....	903	Determ: of Manganese in. (Auchy).....	677
Manuf. of a Product from Sugar, Ferric Oxide and Chloride of. (P) Stahlschmidt.....	740	Diamonds in. (Frank).....	835
Or Potassium, Manuf. of. (P) Kendall.....	907	Diamonds of. (Kossel).....	682
Peroxide, Estim: of Mercury Salts by. (Schuyten).....	475	Diffusion of Sulphides through. (Campbell).....	906
Presence of, in Aluminium.....	597	Forma: of Blister. (Hogg).....	333
Presence of, in Electrolytic Aluminium. (Moissan).....	204	Furnaces for Heating Iron and. (P) Tucker and Harbord.....	516
Shipment of Sulphide of. (T.R.).....	838	Hardening of. (Howe and Sauvour).....	454
Sulphate, Decomp: of Salt in Prod: of. (P) Thomson and Worsley.....	35	Magnetic Permeability of. (Osterberg).....	204
Sulphide and Sodium Sulphhydrate, Estim: of. (Dobrinier and Schranz).....	743	Manuf. of. (P) Last and Wright.....	516
Sulphide, Solubility of Bismuth Sulphide in. (Stullman).....	678	Mond Producer-Gas applied to the Manuf. of. (Darby).....	529
Thiosulphate, Solubility of, in Alcohol. (Parmentier).....	565	Presence of Fixed Nitrogen in. (Harbord and Twynam).....	721
Soil, Inoculation of, for Cultiv: of Leguminous Plants. (P) Nobbe and Hiltner.....	462	Prod: of Basic. 1878-93. (T.R.).....	182
Solder for Aluminium. (Richards).....	200	Quenching of Extra Hard. (Osmond).....	117
Solids, Separ: of, from Fluids. (P) Heys. From Hundhausen.....	887	Wire, Hardening, Tempering, and Tinning. (P) Roberts and Cooper.....	457
Solomine in Potatoes. (Meyer).....	210	Steels, Inf: of Heat and Carbon on the Solubility of Phosphorus in. (Campbell and Babcock).....	905
Solution for Use in Casting Copper Insoles. (P) Lant.....	120	Steffen's Sulphuration Process. (Bauman).....	822
Solutions of Definite Strengths, App: for Prep: (P) Roberts.....	887	Sterilising App: (P) Boul. From Davidson.....	131
Solvay Process in the United States.....	806	App: (P) Kuhn.....	288
Solvents, Estim: the Efficiency of Gold. (Sharwood).....	617	App: (P) Pfeiff.....	609
Extract: of Fats, Oils, &c. by Volatile. (P) Merz.....	792	Stirrer, Auto-Pneumatic. (Brearley).....	741
For Induline Dyestuffs. (Gassmann).....	584	Stone Blocks, App: for Manuf. of Artifi: (P) Jantzen.....	452
Manuf. of Gold. (P) Head.....	37	Cements for Making Mortars for Artifi: (P) Weckwarth and Hoeft.....	36
Separ: Oil from its Volatile. (P) Metzger.....	817	Ceramic, obtained by Devitrification of Glass. (Garchey).....	545
Separ: Oleaginous Mat: from. (P) Lester and Rocio.....	283	Manuf. of Artifi: (P) Arndt and de Bruyn.....	452
Soot, Recovery of, from Products of Furnaces. (P) Mugna.....	466	Manuf. of Artifi: (P) Boul. From Thys.....	729
Sorbosic, Ammonia Deriv: of. (de Bruyn and van Leent).....	683	Manuf. of Artifi: (P) Metcalf and Wrightson.....	452
Spain, Excessive Manuring in.....	602	Manuf. of Artifi: (P) Thompson. From La Soc: Anonyme la Neo-Litho.....	452, 545
Manuf. of Sorolum Sugar in. (Schack-Sommer).....	155	Manuf. of Artifi: Vitreous. (P) Hirsch.....	545
Min: and Metal Trade of. (T.R.).....	627	Or Bricks, Manuf. of Weatherproof. (P) Kleber.....	653
Oleo-Naphtha and Lubricating Oils of. (T.R.).....	225	Prod: of Artifi: (P) Preussner.....	904
Sugar in. (T.R.).....	628	Stoneware, Hungarian.....	358
Treatment of Mercury Ores in the Asturias.....	723	Storage Batteries. See under Batteries.....	
Specification of Iron Drum for Carriage of Ether, &c. (T.R.).....	483	Stoves or Furnaces, Liquid Fuel. (P) Mills. From Carmien and Yvonnet.....	705
Spermaceti, Charac: of. (Kebler).....	206	Strainer Plates used in the Manuf. of Paper. (P) Watson.....	291
Spirit, App: for Gasifying. (P) Yang. From Aschner.....	443	Strawboards, Turning Yellow of the White Paper Coating.....	370
Estim: of Fuel Oil in Fine. (Glasenapp).....	140	Street Lighting, Incandescent Alcohol Lamps for.....	530
Light, Comparison of Incandescent, with other Light. (Fischer).....	581	Strychnine, Characterisation of. (Formanek).....	53
Materials for Denaturing. (T.R.).....	685	Localisation of. (Sauvan).....	736
Prod: of, from Asphodel and Squill. (Riviere and Bailhache).....	606	Sugar, Action of, on Ammoniacal Silver Nitrate. (Henderson).....	222
Trade of Berlin. (T.R.).....	685	App: for Melting. (P) Blake.....	528
Spirits, (Class XVII.)... 43, 126, 210, 287, 366, 463, 552, 606, 664, 731, 823, 913.....		Aqueous Digestion of.....	419
Distill: in Great Britain. (T.R.).....	929	Boiling and Crystallisation of Low Products. (Sachs).....	821
Excise Duty on. (T.R.).....	929	Bush. (Hesse).....	555

LIST OF ERRATA.

Page.	Column.	Line.	Description.
1895.			
269	1	2	From bottom: for "sulphuric acid" read "nitric acid."
1896.			
28	1	1 & 2	Delete "compound with," and for "α-naphthylamine sodium sulphonate," read "α-naphthalene sulphonic acid salt."
49	2	1	Top: for "greater" read "less."
106	2	7	From table: for "per ton" read "per 1,000 lb."
106	Table, last column, heading to right: for "per ton" read "per 1,000."
107	1	4	From bottom: for "per ton" read "per 1,000 lb.," and bottom line, for "per ton" read "per 1,000."
179	2	..	Title of paper: for "C. W. Thompson" read "G. W. Thompson."
272	1	18	From top: for "cochineal" read "cochineal."
296	2	31	From bottom: after "furnace" insert the words "fill the copper fuses."
460	1	..	Bottom line: for "saave" read "sanve."
732	2	..	"Denaturing Alcohol." In this article, "Methylene" is to be understood to mean crude methyl alcohol, or wood spirit.

THE JOURNAL OF THE Society of Chemical Industry.

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 1.—Vol. XV.]

JANUARY 31, 1896.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, Bart., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
Dr. W. H. Perkin, F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.
Sir John Evans, K.C.B., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
Dr. T. E. Thorpe, LL.D., F.R.S.	1894—1895.

COUNCIL FOR YEAR ENDING JULY, 1896.

President: Thos. Tyrer.

Vice-Presidents:

Sir F. A. Abel, Bart., F.R.S.	T. Fairley.
Horace T. Brown, F.R.S.	Boverton Redwood.
John Calderwood.	Sir H. E. Roscoe, M.P., F.R.S.
Chas. Dreyfus.	E. C. C. Stanford.
Dr. A. Dupré, F.R.S.	Dr. T. E. Thorpe, LL.D., F.R.S.
Sir John Evans, K.C.B., F.R.S.	Prof. W. A. Tilden, F.R.S.

Ordinary Members of Council:

J. S. MacArthur.	C. C. Hutchinson.
C. A. Fawcitt.	Ivan Levinstein.
R. Le Neve Foster.	Sir Robt. Pullar.
W. Douglas Herman.	G. N. Stoker.
David Howard.	Wm. Thorp, B.Sc.
Prof. A. K. Huntington.	Frank Wilson.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

NOTICES.

Notice is hereby given that, in accordance with the alterations in Rule 27 sanctioned at the Annual General Meeting in Edinburgh, all new members elected after January 1st, 1895, will be required to pay an entrance fee of one guinea. In accordance with the same rule the Life Composition Fee is now 20*l.*, instead of 15*l.* as heretofore.

COLLECTIVE INDEX.

A collective index, embracing the whole Journal from the Proceedings of the First Annual General Meeting, 1881, to the close of 1895, is now in preparation, and will be ready in the current year. It will contain both a subject-matter and authors' names portion and will be a volume of about 500 pages, uniform in size with the Journal.

The prices will be as follows:—

To Members (see Rules 25 and 27) who make application with remittance, not later than June 30, 1896.....	Each copy	5s.
To Members (see Rules 25 and 27) who make later application; Libraries, Corporations, and Exchanges on the Society's List, and Past Members (see Rule 30).....	Each copy	10s.
To Subscribers.....		12s. 6d.
To others.....		15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

LIST OF MEMBERS ELECTED 23rd JANUARY 1896.

- Adler, Dr. Leon N., Adler Colour and Chemical Works, 95-98, Maiden Lane, New York, U.S.A., Manufacturing Chemist.
- Caven, Robt. M., University College, Nottingham, Lecturer and Demonstrator in Chemistry.
- Davies, Llewellyn J., 8, Wordsworth Avenue, Cardiff, Assistant Analyst.
- Dawson, Geo., Reddish Chemical Works, near Stockport, Technical Chemist.
- Deakin, E. C., Ryecroft House, Belmont, Bolton, Dyer.
- De Lessing, G. C., 589, Lexington Avenue, New York City, U.S.A., Manufacturing Chemist.
- Elliott, Dr. J. F., c/o Grinwade and Co., 82, Bishopsgate Street, E.C., Manufacturing Chemist.
- Eyekeus, Oscar, 14, rue Bleue, Paris, France, Chemical Manure Manufacturer.
- Ferguson, J. Hart, Loch Katrine Distillery, Camlachie, Glasgow, Distillery Manager.
- Graves, Geo. H., Fairfield Chemical Works, Bridgeport, Conn., U.S.A., Manufacturing Chemist.
- Hardman, Rd. B., Fernhill Mills, Bury, Lancashire, Woollen Manufacturer.
- Hargreaves, Jas., Farnworth, Widnes, Lancashire, Chemical Engineer.
- Isaacs, Louis A., 180, Belsize Road, West Hampstead, N.W., Manufacturer.
- Lobry de Bruyn, Dr. C. A., 2^e Parkstraat 151, Amsterdam, Holland, Navy Chemist.
- Meggitt, Loxley, c/o Saml. Meggitt and Sons, Ltd., Mansfield, Notts, Analytical Chemist.
- Ogilvy, D. J., Gest Street, and C.H. & O.R.R., Cincinnati, Ohio, U.S.A., Manufacturing Chemist.
- Osmond, Jno. H., c/o Messrs. Smith, Bell, and Co., Manila, Sugar Works and Technical Chemist.
- Parr, Saml. W., Chemical Laboratory, University of Illinois, Urbana, Ill., U.S.A., Professor of Applied Chemistry.
- Parry, John, Technical Laboratory, Newport, Mon., Analytical Chemist.
- Rosenheim, Dr. Otto, 68, Belsize Park Gardens, Hampstead, N.W., Analytical and Research Chemist.
- Round, Wm., 10, Northampton Street, Birmingham, Analytical Chemist.
- Sadtler, Dr. Saml. S., 204, North 34th Street, Philadelphia, Pa., U.S.A., Chemist (Customs).
- Seymour, Wm., Africander Gold Mining Co., Box 38, Klerksdorp, S.A.R., Chemist.
- Seldner, Rudolph, 217, Jefferson Avenue, Brooklyn, N.Y., U.S.A., Instructor in Chemistry.
- Sharpley, Wm. P., Ditton Copper Works, Widnes, Analytical Chemist.

- Smith, T. Reader, Urban District Council, Kettering, Surveyor and Civil Engineer.
- Smith, Walter E., 47, Jenkins Street, Providence, R.I., U.S.A., Instructor in Chemistry.
- Stafford, Charles H., c/o the Birkacre Printing Co., Birkacre, Chorley, Colourist.
- Thomsen, Alonzo L., 16, West Madison Street, Baltimore, Md., U.S.A., Manufacturing Chemist.
- Tonkin, John, 294, E. 34th Street, Bayonne City, N.J., U.S.A., Manufacturing Chemist.
- Welch, Thos., Green Vale Printworks, Westhoughton, Lancashire, Calico Printer.
- White, G. Rantoul, Exeter, New Hampshire, U.S.A., Chemist.
- Woolf, Julian, 1, Marlborough Place, St. John's Wood, N.W., Manufacturer.
- Zurborn, Otto, Grevenbroich, Rheinprovinz, Germany, Engineer.

CHANGES OF ADDRESS.

- Adrianee, J. S., 10 Broadway; 126, East 34th Street, New York, U.S.A.
- Baker, Theodore, 10 Oakland; Box 97, Belford, N.J., U.S.A.
- Bateson, P., 10 Emsworth; Oakfield, Penny Lane, Wavertree, Liverpool.
- Binney, H. A., 10 St. Helens; Rainhill, near Liverpool.
- Bird, W. R., 10 Albion Street; 12, Gordon Road, New Swinden.
- Booth, F. W., 10 The Gardens; Station Road, Whittington Moor, Chesterfield.
- Brown, Robt., 10 Winington Hill; The Firs, Hartford, Cheshire.
- Chapman, A. C., 10 Euston Buildings; East India Chambers, 23, Leadenhall Street, E.C.
- Clayton, R. H., 10 Rochdale Road; 61, Higher Ardwick, Manchester.
- Colquhoun, Wm., 10 Cardiff; c/o Francis Morton and Co., Ltd., Garston, near Liverpool.
- Cook, J. Williams, 10 St. Mary Axe; London and Provincial Dyeworks, Hackney Wick, N.E.
- Corbould, W. H., 10 Coolgardie; Harman's Reward Gold Mine, Kalgoorlie, Western Australia.
- Crawley, A. H., 10 Liverpool; Schladeren a d Sieg, Rhenish Prussia.
- Davidson, R., 10 15; 40, Lilybank Road, Dundee.
- Davies, W. E., 10 Beaumaris; c/o Messrs. Easton, Anderson, and Gooldeen, Ltd., Erith, Kent.
- Dyson, Herbert, 10 Middlesbrough; West View House, Apperley Bridge, near Leeds.
- Encquist, Jno., 10 Long Island; 592, Clinton Avenue, Brooklyn, N.Y., U.S.A.
- Fischer, Albert, 10 Billiter Street; 75, Palmerston Buildings, London, E.C.
- Fletcher, E. Morley, 10 Caterham; 1, Moor View, Hyde Park, Leeds.
- Fox, Thos., jr., 10 Court; Tonedale, Wellington, Somerset.
- Gair, Wm., 10 Newcastle; 125, Frederick Road, Aston, Birmingham.
- Gibbins, H. B., 10 Manor Park; 177, Redland Road, Bristol.
- Gratama, Dr. W. D., 10 Delft; Huize Kraayenburg, Ryswyk, Z.H., Holland.
- Green, J. E., 10 Durham; 1, Queen's Road, Elmston, near Manchester.
- Grossmann, Dr. J., 10 Hemdham Vale; Harpurhey Chemical Works, Manchester.
- Hay, Alex. B.; Journals to Kelvinock Chemical Works, Maryhill, Glasgow.
- Heron, Jno., 10 Clapham; 110, Fenchurch Street, London, E.C.

- Heyl, J. Edw., 10 Balham ; 38, Bury New Road, Higher Broughton, Manchester.
- Hogben, Walter, 10 Newcastle ; 18, Hunter's Road, Handsworth, Birmingham.
- Hooper, E. F., 10 Beckenham ; Wear Fuel Works, Hendon Dock, Sunderland.
- Jones, David S., 10 Coatbridge ; c/o Lisbon Berlyn Co., Ltd., Pilgrim's Rest, Lydenburg, S.A.R.
- Kawakita, M., 10 Werft Strasse ; Kant Strasse 24¹¹¹, Charlottenburg, Berlin.
- Lander, A. H. ; Journals to 7, Carlyle Road, Edgbaston, Birmingham.
- Loewenthal, Dr. R., 10 Magasinstrasse ; Markusstrasse 49, Berlin, O.
- Lowe, Jas. S., 10 Edinburgh ; c/o Mauritius Estates and Assets Co., Ltd., Port Louis, Mauritius.

SESSION 1895-96.

February 3rd, 1896.—Mr. Walter F. Reid. "Manufacture of Linoleum."

Meeting held Monday, January 6th, 1896.

MR. B. E. R. NEWLANDS IN THE CHAIR.

A STUDY OF COMPARATIVE AFFINITIES IN
THE CASE OF CERTAIN SALTS OF AMMONIUM,
SODIUM, &c.

BY WATSON SMITH.

A known weight of ammonium sulphate was heated in an air-bath to between 270° and 310° C., allowing the latter temperature to be gradually attained. Steam was at the same time passed through the apparatus. The issuing steam was cooled by a condenser, and the vapours, &c., collected in normal hydrochloric acid. It was thus found that one-half of the ammonia was expelled from the salt. The residual salt, it was found, melted at 140° C., and solidified at 128°, the temperature on solidification rising to 130° C. But on one occasion, whilst heating up the sulphate of ammonium in an air-bath and passing steam through the mass, the steam was accidentally cut off. The result was an immediate evolution of sulphurous acid and ammonia, forming ammonium sulphite, which at once stopped up the tubes of the apparatus. This phenomenon was never observed when steam was employed, *i.e.*, no SO₂ could be detected by the smell, and only a very slight turbidity was produced in the distillate with barium chloride. In other words, then, it would be possible to prepare a tolerably pure ammonia solution by heating ammonium sulphate alone and passing steam through the mass.

This steam process was, however, a very slow one for the complete production of a residue containing but one-half of the original ammonia, and a quantity of ammonium sulphate was heated in a platinum dish, as described in this Journal, 1895, 629.

In an analysis of the ammonium bisulphate obtained, the numbers were as follows:—

	Found.	Calculated.
	Per Cent.	Per Cent.
Ammonia.....	15.965	14.78
Free acid	42.90	42.61
		NH ₄ HSO ₄

In answer to the question, "What actually takes place at the commonly repeated melting point of ammonium sulphate, viz., 146° C.?" (This Journal, 1895, 629.) Dry crystals of ammonium sulphate begin to decrepitate at about 290° C., ammonia coming off very perceptibly at 250° C. If superheated steam be passed through the mass of heated crystals, ammonia comes off very perceptibly at 200° C. This was an experiment in which, however, only good-sized crystals of the salt were taken. The experiments now to be described will do more than answer the question above recorded.

I.—SOLID AMMONIUM SULPHATE.

1. A quantity of pure ammonium sulphate was powdered pretty finely and introduced into a small retort connected with a condenser. A thermometer was placed amongst the salt in the retort, and the latter was slowly heated on the sand-bath. At 180° C. ammonia could be distinctly perceived at the end of the condenser, and at 250° C. drops of ammoniacal water began to fall. The salt did not melt until 300° C. was reached, when the portion nearest the glass in the interior of the retort began to fuse.

2. Some powdered ammonium sulphate was placed in a test tube with perforated cork and two pieces of bent tube. One of the tubes connected the test tube with an air blast, and a gentle but steady stream of moist air was passed through whilst the temperature was being gradually raised on the sand-bath. Another thermometer was placed in the sand close to the side of the test tube, and the temperature thus given was taken.

Ammonia, it was found, first became perceptible to red litmus paper at 129° to 125° C.

3. The same experiment was repeated with the powdered salt, using, however, an oil-bath instead of a sand-bath, the thermometer being placed in the oil. The air employed in the blast was passed through dilute sulphuric acid, so that it might carry no ammonia from the external air.

Ammonia became manifest at 177° C.

4. Some more salt was now pulverised in a mortar, and then sifted through linen by means of a Bunsen's bag apparatus. The sulphate, in the form of this impalpable powder, was now treated just as in experiment No. 3.

Ammonia plainly evolved at 105° C. After cooling down and then reheating very gradually, ammonia was detected at 86° C.

These experiments prove how greatly physical condition influences the decomposition point of the sulphate of ammonium by heat.

II.—AMMONIUM SULPHATE. CONCENTRATED SOLUTION.

5. Of course a still greater degree of attenuation is obtained in solution.

It was then discovered that from a concentrated solution of pure ammonium sulphate, ammonia begins to be evolved at a temperature so low as 60° C., and is very decidedly manifest at 65° C. On cooling and then gradually reheating, ammonia was detected as low as 58° C.

6. The concentrated solution of ammonium sulphate which had previously been heated at about 70° C., was now maintained at that temperature for about an hour. Ammonia was evolved the whole time, and at the end thereof, the solution showed a decidedly acid reaction to blue litmus paper. The solution of the sulphate was, to begin with, perfectly neutral.

7.—(a.) Some commercial ammonium sulphate was now dissolved in water. The solution was acid to litmus. Neutralised with ammonia and then evaporated for some time at a temperature about boiling point, keeping up the

level of the liquid with fresh additions of water. The final liquid was distinctly acid.

(b.) Evaporated similarly a concentrated solution of pure sulphate. The result was just the same as in (a.).

In the cases of (a) and (b), when a piece of red litmus paper was held in the vapours evolved by the boiling solutions, it is turned quickly blue. But the experiment becomes striking, when a piece of red litmus of about a superficies of 2 or 3 square inches, is held in the vapours so near the boiling liquid that some of the fine spray comes in contact with it. The red paper turns quickly blue, and then immediately becomes covered with red spots on a blue ground. This is due to the fact that whilst ammoniacal vapours are evolved from the heated liquid, the fine vesicles of the liquid itself have a decidedly acid reaction. Hence the test paper bears witness at one and the same time to (1) the acidity of the liquid and (2) the alkalinity of the vapours.

These experiments have a technical bearing, indicating the losses of ammonia that must follow any attempt to concentrate by evaporation solutions of ammonium sulphate so as to reach the crystallising point. Bone distillers who manufacture bone black, animal charcoal, and bone manures, are generally content with a very crude sulphate of ammonia, obtained by neutralising their bone liquors with sulphuric acid. These solutions I have myself seen in course of evaporation in iron pans to the crystallising point, the liquors being in a very active state of ebullition. There is not the least doubt that considerable losses of ammonia are sustained in such cases, and no doubt as concentration increases and consequently acidity, there will be increased action on the iron pans, with formation of iron sulphate.

But on heating ammonium sulphate, ammonia is not the only constituent driven off; we have already learnt that sulphurous acid is also liable to be set free. An interesting question now unfolds itself:—

What are the precise conditions under which the sulphur trioxide molecule in the sulphate is reduced to sulphur dioxide, and this sulphur dioxide then expelled?

We have already learnt that on heating ammonium sulphate to a temperature of about 270° C. to 300° C., and passing steam through the mass, pure ammoniacal gas is set free and escapes.

(1.) Having regard to the heating of sulphate of ammonium *without steam*, the experiment was tried of heating pure sulphate to from 270° to 280° C. for 19 hours, any vapours evolved being aspirated through water. It was found that 14 per cent. of the one equivalent of NH₃ was evolved, and that a little over 0.01 per cent. of the SO₃ was lost as SO₂.

(2.) Powdered ammonium sulphate was heated to from 300° to 310° C. for 12 hours, aspirating through water and afterwards through normal acid.

19 per cent. of NH₃ (of the one equiv.) were found, and 0.016 per cent. SO₂ lost as SO₃.

(3.) Powdered sulphate heated to 275°–280° C. for 12 hours, aspirating so as to create a more considerable vacuum, and passing first through water and then acid, as before:—Found 37.4 per cent. NH₃; and no SO₂ lost.

It was found that the sample which had lost 19 per cent. NH₃ (experiment No. 2), when dissolved in water and mixed with zinc powder, evolved hydrogen gas freely.

(4.) (NH₄)₂SO₄ heated for 8 hours at 300° C. in a test tube of hard glass, aspirating the gases through water and then normal acid, with considerable suction, yielded 99.1 per cent. of the one equiv. of NH₃, and 0.146 SO₂ lost as SO₃.

(5.) (NH₄)₂SO₄ heated for 13 hours from 310°–315° C. Evolved: 99.4 per cent. NH₃. After the 13 hours' heating, on increasing the current of air by aspiration, ammonium sulphites began to sublime abundantly, and would soon have stopped up the connecting tubes. The bath for heating the tubes, was one of "fusible metal." In one experiment, in which a tube of soft soda-glass was used, 3.3 grms. of (NH₄)₂SO₄ were heated for 15 hours at 300° C. 100.4 per cent. of NH₃ was found, but also 0.825 per cent. SO₂ lost as SO₃, and also 0.16 per cent. SO₂ lost as sublimed sulphite. However, on removing the coat of fusible alloy from the bottom of the test tube, it was found that the glass had been attacked throughout and thoroughly decomposed

by the ammonium bisulphate formed. This, together with the increased percentage of SO_2 evolved, are evidences, together accounting for the large percentage of ammonia found, some NH_3 of the NH_4HSO_4 having evidently been sacrificed.

6.6 grms. of ammonium sulphate were heated to between 270°C . and rising to 310°C ., steam being meantime passed through. On condensing and testing, it was found that just about the full one equiv. of ammonia had been expelled and absorbed in the acid used.

Glancing at a statement made (this Journal, 1895, 629) as to the disintegration of $(\text{NH}_4)_2\text{SO}_4$ at high temperatures: "*If NH_3 thus loses H to reduce SO_3 in the molecule of $(\text{NH}_4)_2\text{SO}_4$ or NH_4HSO_4 to SO_2 , what actually becomes of the nitrogen of such NH_3 ?*"

Some ammonium bisulphate (NH_4HSO_4) was placed in a small bulb with bent tube, such that but little air was enclosed. The tube dipped under caustic soda solution and entered the lower part of the graduated test tube acting as gas receiver, and also filled with caustic soda. The gases first evolved were allowed to escape so as to remove air from the bulb apparatus. It was at length noticed that when heating from 300 — 350°C ., bubbles escaping at the end of the tube were completely absorbed by the soda, when the stem was placed under the orifice of the test tube. The fact was now observed that whilst SO_2 seemed to be abundantly evolved, it was nearly all absorbed by the soda, no permanent gas at first collecting in the test tube, and hence very little nitrogen was concurrently liberated from the NH_4HSO_4 . At last, on applying considerably more heat (bare flame of the lamp), some permanent gas collected in the test tube, but apparently a minute proportion in comparison with the volume of the SO_2 evolved. The small amount of residual gas collected, extinguished a taper, and did not render lime-water turbid, and it appeared to be nitrogen (no oxygen could be detected amongst it). As stated (this Journal, 1895, 630), nitrogen only appears to be perceptibly evolved at temperatures between 360° and 400°C ., whilst with a fair amount of freedom at 450°C . and above. See also J. Chem. Soc., 1884, 92, Ramsay and Young, where it is shown that "The temperature at which ammonia begins to decompose, under the most favourable circumstances, lies a little below 500°C .". In the present case, of course, the ammonia is being heated in presence of an oxidising agent (SO_3). At the latter temperature, though but proportionately a small fraction of the nitrogen of the ammonia in the salt had been evolved as nitrogen, it was found that the SO_3 in the residue had been largely reduced to SO_2 , i.e., the residue consisted largely, almost wholly, of sulphites.

At 350°C ., whilst SO_2 was decidedly formed and evolved free, very little nitrogen could be detected, i.e., very little uncondensable and inert gas.

The question arises, then, "*If SO_2 is evolved and yet very little free nitrogen from the NH_4HSO_4 , can any other reaction which expresses the change in part, if not wholly, be regarded as admissible; along with that expressed by the equation $3\text{NH}_4\text{HSO}_4 = \text{N}_2 + \text{NH}_4\text{HSO}_3 + 5\text{H}_2\text{O} + 2\text{SO}_2$?*"

I had at one time believed I had obtained evidence of an intermediate formation of hydrazine sulphate, thus:— $2\text{NH}_4\text{HSO}_4 = \text{N}_2\text{H}_4\text{SO}_4 + \text{H}_2\text{O} + 2\text{SO}_2$; small portions of the substance being heated, at times giving an instantaneous dark precipitate of Ag in the cold, with ammoniacal silver nitrate. Curtius, Ber., 20, 1634. Of course, were this the case one would expect this compound at the elevated temperature, soon to break down again with evolution of N and SO_2 , thus:— $\text{N}_2\text{H}_4\text{SO}_4 + \text{NH}_4\text{HSO}_4 = \text{N}_2 + \text{SO}_2 + 3\text{H}_2\text{O} + \text{NH}_4\text{HSO}_3$. But until I can get more tangible evidence of such an interesting reaction, I must adopt the following, in which at the high temperature ammonium bisulphate breaks down into nitrogen, bisulphite, water and sulphur dioxide. This reaction also accounts for a considerable excess of SO_2 :—

(See also this Journal, 1895, 629.)

With regard to Kjeldahl's method, I may state, that though ammonium sulphate, as I have shown, is considerably

decomposed and modified on heating to temperatures below 300°C ., yet on heating some pure ammonium sulphate in presence of excess of concentrated sulphuric acid up to 300°C ., not a trace of NH_3 was evolved, which perfectly bears out the fact of the validity of this process.

I may just mention here that normal ammonium sulphite, on heating, decomposes like the sulphate, yielding ammonia and bisulphite.

VARIOUS DECOMPOSITIONS OF INTEREST BY MEANS OF AMMONIUM BISULPHATE.

Oxalic Acid.—When ammonium bisulphate is fused and oxalic acid is introduced into it, decomposition of the latter at once takes place with evolution of CO_2 and CO.

REACTION OF AMMONIUM CHLORIDE WITH NORMAL AND ACID AMMONIUM SULPHATE.

Mixed Solutions.—5 grms. of ammonium sulphate and 2.026 grms. of ammonium chloride (i.e., equiv. weights) were placed in a suitable apparatus along with 20 c.c. of water. The liquid was now boiled and evaporated. It was observed that ammonia was copiously evolved as the solution became more concentrated. After about 8—9 hours' boiling, some little water being added from time to time, it was found that the escaping vapours had acquired an acid reaction, and that hydrochloric acid was coming off. After some time the test tube was filled again with water to the 20-c.c. mark and boiling continued. It was now found that ammonia was evolved, and this again continued until the solution became somewhat concentrated, when this particular reaction seemed to expend itself, then become reversed, and once more hydrochloric acid was evolved.

Mixed Solids.—Similar weights of the two salts were now taken, thoroughly mixed and the dry mixture heated in the sand bath, which was afterwards changed for a bath of fusible metal, in which a thermometer was placed. The apparatus was connected with a water-pump, so that the heating process was conducted under partial vacuum. The temperature was gradually taken up to 300°C ., when in about $\frac{1}{2}$ th of an hour the escaping vapours became acid. After nearly 10 hours' heating, with slow aspiration all the time, the litmus began to turn blue again through reversal of the reaction and evolution of ammonia. In 3 hours more HCl was evolved, and in $\frac{1}{2}$ hours more, ammonia. The rationale of this curious process of reversing reactions is, I believe, this:—Heat causes the ammonium sulphate to part with a certain proportion of its ammonia, and when a certain and sufficient quantity of bisulphate is thus formed, the latter attacks the ammonium chloride, takes from it some of its ammonia, and generates hydrochloric acid, which escapes. This re-saturation and so recovery of balance of the sulphate proceeds up to a given point, determined doubtless by the joint factors of temperature and mass, when balance is again upset, and the re-saturated sulphate again parts with ammonia, and so on. Thus we have a singular case in which from one saline mixture, alternately ammonia and hydrochloric acid is evolved by the mere application and maintenance of heat. Among the ammonia and hydrochloric acid thus evolved there are respectively ammonium sulphites and sulphurous acid to some extent present.

The determination was now made of the nature and extent of the reaction of ammonium bisulphate on ammonium chloride. To begin with it was found that ammonium bisulphate, NH_4HSO_4 , when heated with ammonium chloride, NH_4Cl , yields normal ammonium sulphate and hydrochloric acid—

However, this equation, like many others, would not guide the operator to a practical realisation of the reaction as stated. If this equation did hold good in practice, the death-blow to the Leblanc soda industry would already have been struck, for we have seen that pure ammonia can be obtained by suitably heating normal ammonium sulphate. Now what takes place when *equivalent weights* of ammonium bisulphate and ammonium chloride are heated together, is this:—A certain proportion of the chloride is decomposed by the bisulphate, yielding HCl and $(\text{NH}_4)_2\text{SO}_4$; the amount

and degree of acidity of the mixture at length become so reduced by dilution that the remaining NH_4Cl ceases to be acted upon. Further heating, and at somewhat higher temperatures, would then only lead to a reversal of reaction, with evolution of ammonia. This would lead to increased acidity (further formation of NH_4HSO_4), and after a time another reversal, the NH_4HSO_4 reacting once more on some residual NH_4Cl to form more HCl , and so on. It thus became clear that to effect the complete decomposition of a given quantity of ammonium chloride, a very large excess of bisulphate of ammonium would be necessary. For example, it is found that on heating in a special apparatus, 2 grms. of NH_4Cl with 20 grms. of NH_4HSO_4 , 92 per cent. of the HCl was driven off, whilst with 2 grms. of NH_4Cl with 30 grms. of NH_4HSO_4 , as much as 95 and 97.6 per cent. respectively of HCl were obtained in two experiments. (A specimen of fuming hydrochloric acid prepared from HCl thus evolved, was now exhibited.) Moreover, it was found that after thus obtaining the HCl , on heating the residue in the hopes of now expelling the ammonia at the same time taken up from the NH_4Cl , only a fraction thereof is obtained, the remainder being obstinately retained, and at the temperature required to expel it, a considerable loss is sustained by formation of sulphites.

It will be noted that in this latter case, the effort is being made to expel ammonia in presence of a large excess of ammonium bisulphate, a condition approaching that which confers so much value upon the Kjeldahl's process.

To show the extent of the reaction if a smaller excess of ammonium bisulphate be used with the ammonium chloride, the following experiments were tried:—

1 equiv. of NH_4Cl was heated in concentrated solution, with 2 equivs. of NH_4HSO_4 , and heating was continued until NH_3 began to be evolved. 53 per cent. of the HCl obtained.

Two experiments were now tried with above mixture, dry, when in one case 30.5 per cent. and in the other 42 per cent. of the HCl in the NH_4Cl was obtained. In the second experiment the vapours were passed through fused and heated NH_4HSO_4 . By modifying the apparatus so that if any NH_4Cl sublimed, it would be decomposed in a further quantity of NH_4HSO_4 , and improving the system generally, 72 per cent. of HCl was obtained. But along with HCl , SO_2 was also obtained, indicating some reduction.

A further experiment was now made. Having prepared some acid ammonium sulphate by heating the normal salt, common salt (NaCl) was added to the hot fused liquid. Hydrochloric acid was copiously evolved, and on further addition of NaCl , the reaction came to an end, with formation doubtless of NaNH_2SO_4 . This on further heating evolved ammonia, and at length NaHSO_4 remained behind. But on addition of NaCl to the fused NH_4HSO_4 , do not think that the formation of NaNH_2SO_4 is a complete formation, or that it is unattended by side issues, which represent on a working scale, by-products. The reaction proceeds up to a point, at which the acidity of the mixture still containing some NH_4HSO_4 , is so reduced, that it refuses further to act upon the NaCl . If now, about such a point of unstable equilibrium, the heat be further pushed, I have always found that a considerable tendency, the maximum tendency to a reducing action, arises, with formation of sulphurous acid, and so of sulphites.

A process has been devised in time past for obtaining at one and the same time ammonia and bisulphate of soda, by heating a mixture of equivalent quantities of ammonium sulphate and sodium sulphate, and injecting steam into the liquid mass. The bisulphate of soda is then further heated with common salt, with production of hydrochloric acid and regeneration of normal sodium sulphate.

This is a portion of the beautiful process of Carey, Gaskell, and Hurter (this Journal, 1885, 117). What I wish now to show is that something approaching the reverse of this process will also operate. If ammonium sulphate be heated, till one-half its ammonia is expelled, bisulphate remaining, and then to this in a fused state, sodium chloride be added, hydrochloric acid is abundantly evolved, and sodium ammonium sulphate produced. But reduction of SO_3 to SO_2 , with formation of sulphites, also occurs, and the reaction is not complete. On further heating, NH_4NaSO_4

yields up its NH_3 and leaves NaHSO_4 . If to this NaHSO_4 in the fused state NH_4Cl were added, HCl would be generated, and NaNH_2SO_4 obtained, providing the temperature of the fused mass were kept sufficiently low, and other suitable conditions provided. Yet this reaction could not be completed, for reasons already given, and the attempt would lead to the reduction of SO_3 to SO_2 , besides sublimation of NH_4Cl . What double salt was formed, would on further heating be, of course, decomposed, with liberation of ammonia, and re-formation of sodium bisulphate. If you ask me, "Could a process be based upon such a reaction as this for yielding ammonia and hydrochloric acid?" I reply that such a process could scarcely be carried out as a commercial success. Nor would the case be materially improved, if a commencement were made with fused bisulphate of soda, and to this were added ammonium chloride, HCl being generated and NH_4NaSO_4 produced, plus a necessary excess balance of NaHSO_4 , without which the reaction would not be completed. It is true that on heating, with injection of steam, ammonia would be expelled, and sodium bisulphate reproduced, but unfortunately, at the temperature required to complete this reaction, the SO_3 molecule would be to some extent reduced, and some of the ammonia would come over as sulphites, blocking up tubes and pipes most inconveniently. But as you may anticipate, the incompleteness of reaction does not stand still in the cycles of process; it increases, and at length brings the work to a standstill. The decomposition, with formation of sulphites, must always be accounted a constant in any process in which heat of any considerable degree is used, when ammonia is liberated in presence of ammonium sulphate or bisulphate. This evil is avoided to a considerable extent, though not altogether, if steam be injected, but then the process becomes a long one to complete, as the superheating temperature must be moderate.

But unfortunately, and further, the very condition for obtaining a good yield of HCl , viz., large excess of bisulphate, forms also the condition for very special stability of the ammonia fixed by that excess, which consequently suffers only very partial expulsion by subsequent heating.

Chlorine from Ammonium Chloride.—The next point I turned my attention to was the possibility of utilising the reaction of ammonium bisulphate upon ammonium chloride for the sake of producing chlorine directly. On heating together a mixture of ammonium bisulphate, chloride, and Weldon mud, under suitable conditions, chlorine is generated, and on being passed into potassium iodide solution, iodine is set free. On heating 1 equiv. NH_4Cl , 2 equivs. of MnO_2 and 4 equivs. of NH_4HSO_4 together with a little water, for about half an hour, aspirating the gases through potassium iodide, free iodine was liberated equivalent to a liberation of 12 per cent. of the combined chlorine. The above experiment was repeated with an increase of MnO_2 to 4 equivs., when 14.2 per cent. of chlorine was obtained.

The experiment was now varied by taking 1 equiv. of NaCl instead of NH_4Cl , when in one case 18.3 per cent. and in another 22.9 per cent. of Cl were obtained. Another variation was now tried, with better success. 1 equiv. of NH_4Cl and 4 equivs. of NaHSO_4 were heated with 1 equiv. of MnO_2 and a little water, in a test tube made of hard glass. Iodine equivalent to 81.5 per cent. of chlorine was liberated. In another experiment this was increased to 83.5 per cent. of chlorine.

Now this process, judged from the results just stated, has so far a somewhat favourable appearance technologically. It looks as if, with a little improvement, something might be done with it. When bisulphate of soda thus acts upon ammonium chloride in presence of MnO_2 , we may say, to put it briefly,—

The next step of importance would be the possible liberation of the NH_3 in this salt by heat suitably applied, so that that NH_3 should be recovered, leaving the acid salt also available for further use. Of course, the reaction with NH_4Cl (omitting MnO_2) so as to produce HCl , would be a useful one, if available, as already pointed out. To ascertain whether such a reaction would be a smooth one, I prepared some of the double salt NaNH_2SO_4 . 36.796 grms. of 89.2 per cent.

caustic soda, were dissolved in water and treated with 45.5 c.c. of 96.1 per cent. sulphuric acid. Excess of ammonia was added, and the solution was evaporated to the crystallising point. Fine crystals were obtained of the double salt. Now, W. A. Miller, in his work, *Miller's Elements* (1864), and Dammier, in his *Handbuch der anorg. Chem.* II. [2], 268, write the formula of this salt as $\text{NH}_4\text{NaSO}_4 \cdot 2\text{H}_2\text{O}$. By direct estimation of NH_4 in the salt (as NH_3), 9.4 per cent. of NH_4 was found. $\text{NH}_4\text{NaSO}_4 \cdot 2\text{H}_2\text{O}$ requires 10.4 per cent., whilst—

requires 9.42 per cent. of NH_4 . A determination of SO_4 gave 50.84 instead of 50.26 per cent. required by the formula $\text{NH}_4\text{NaSO}_4 \cdot 3\text{H}_2\text{O}$. On ignition, 1.1851 grms. of salt left 0.4751 grm. $\text{Na}_2\text{SO}_4 = 12.99$ per cent. Na. $\text{NaNH}_4\text{SO}_4 \cdot 3\text{H}_2\text{O}$ contains 12.04 per cent. Na. The attempt was made to determine the NH_4 and H_2O together by heating a known weight of the salt gently in a platinum crucible until SO_2 just became perceptible. Two determinations were made, with the following results:—

(1.) 38.6 per cent. loss. (2.) 39.1 per cent. loss. Mean = 38.85. Deducting in each case the NH_3 already determined, the content of water would be $38.85 - 9.10 = 29.75$. This last result for water could not be much relied upon on account of the incipient evolution of SO_2 . It was further discovered that at the point at which acid fumes began to be set free, there still actually remained in the residue in the crucible, some ammonia. The effort was now made to push the heating process somewhat further, when it was found that as the last traces of ammonia were evolved, they came off as sulphite along with SO_2 , and then SO_3 followed. Thus, then, the failure of this latter process for water determination, as one of quantitative estimation, confirmed a tendency, already alluded to, which would probably render futile the attempt to utilise the reaction—

and especially if a considerable excess of NaHSO_4 were present, the intention being to again act with this acid sodium sulphate upon a further molecule of NH_4Cl . In presence of increased excess of NaHSO_4 , the NH_3 becomes more and more firmly fixed, till at length the exalted temperature sufficing to displace it, also suffices to induce reduction of SO_3 .

If, on the other hand, the refractory portion of the NH_3 be left in combination, only a reduced area of reaction would be obtained for the next stage; and in large-scale working especially this area of reaction would become still further reduced. We arrive, then, at two facts:—

(1.) That the double salt NH_4NaSO_4 is probably one crystallising with $3\text{H}_2\text{O}$, and not $2\text{H}_2\text{O}$ as generally stated.

(2.) That not only is ammonia very stable in presence of excess of strong sulphuric acid (Kjeldahl), but its stability also increases in like manner, in presence of excess of an alkaline bisulphate; indeed, to such an extent that the heat required to dissociate it, also suffices to bring about reduction of SO_3 to SO_2 .

A few experiments were now made with portions of the pure double sodium ammonium sulphate.

1. A quantity of the double salt was heated in a platinum crucible. The dried salt first melts and then evolves ammonia, but at the closing stage of this evolution does not perceptibly evolve SO_2 , the next stage being characterised by evolution of white pungent fumes of SO_3 —

2. 3 grms. of double salt heated in a hard glass test tube in a bath of fusible metal for 12 hours at $300^\circ - 305^\circ \text{C}$., aspirating the vapours through water and normal sulphuric acid. On titration, it was found that 68.75 per cent. of the NH_3 had been given off. Testing with iodine solution and thiosulphate showed no sulphurous acid had passed over.

3. A concentrated solution of the double salt was heated by means of the oil-bath, air being gently blown first through dilute sulphuric acid and then through the tube containing the heated salt. Ammonia first began to appear (indicated by test paper) at 65°C ., and decidedly at 90°C .

In another experiment, with still more careful observation. First appearance of NH_3 at 58°C .; decided tokens at 80°C .

4. On similarly treating the crystals themselves (not in solution), NH_3 first appeared at 78°C ., and decidedly at 100°C .

It is interesting to note that crystals of the normal ammonium sulphate similarly heated, began to evolve NH_3 at 130°C ., and decidedly at 155°C .

Thus, then, the NH_3 held by NaHSO_4 as the double salt $\text{NH}_4\text{NaSO}_4 \cdot 3\text{H}_2\text{O}$, is much more lightly held, than it is as $(\text{NH}_4)_2\text{SO}_4$, i.e., it is more easily and smoothly expelled.

5. Finally, the following experiment was tried, and it is one offering much technical suggestion:—3 grms. of the double salt were heated in a hard glass test tube in a bath of fusible alloy, so that a Chorley and Baly thermometer could also be used.

Heating was continued for 13 hours at $300 - 305^\circ \text{C}$., the vapours being aspirated through water and then semi-normal sulphuric acid. On back titration it was found that 66.57 per cent. of the NH_3 had been evolved. Tests with iodine and thiosulphate showed that no SO_2 had come over.

After this the tube containing the double salt was connected to two tubes, the first containing semi-normal sulphuric acid, and the second, water containing starch iodide sufficient to induce a pale blue colour. The temperature was raised to 450°C ., and kept at that for nearly an hour, when acid vapours began to appear. Stopped the experiment and titrated the excess of acid, finding that 7.7 per cent. more of NH_3 had come over, but no SO_2 could be detected. The tube was now maintained at 450°C ., for another hour, passing the acid vapours first through water and then water coloured blue with a little iodine and starch paste. Enough SO_2 to decolorise the iodide of starch solution passed over in just under the hour.

a. From the foregoing, it will be plain that though the NH_3 in association with NaHSO_4 as NH_4NaSO_4 , is at first very easily expelled by heat, as the excess of residual NaHSO_4 increases, the stability of the remaining NH_3 rapidly increases, and the latter portions of NH_3 remain more firmly combined with the excess of NaHSO_4 than is the case with a similar excess of NH_4HSO_4 .

b. Also that whereas on heating the double salt NaNH_4SO_4 , ammonia is first evolved, and that later on, the sodium bisulphate left is further resolved into $\text{H}_2\text{O} + \text{SO}_3$ and Na_2SO_4 ; more complexity of decomposition ensues on heating $(\text{NH}_4)_2\text{SO}_4$. For whilst at the outset, ammonia is evolved at moderate temperatures without much loss of SO_3 as SO_2 , the case is different when the condition of ammonium hydrogen sulphate is reached.

c. It is thus interesting, and to technologists may be useful, to note that the breakdown or reduction of the SO_3 group, is not appreciably effected in the expulsion of NH_3 from $(\text{NH}_4)_2\text{SO}_4$ —that can be avoided,—but is effected largely and chiefly by the prolonged action of heat on the ammonium bisulphate left.

I have to acknowledge the zealous help and co-operation of my former assistant, Mr. J. C. Chorley, in the first part of this investigation, and in the latter portion the great care and skill of my present assistant, Mr. Albert Shonk.

DISCUSSION.

The CHAIRMAN considered that all present would agree that Mr. Watson Smith's paper was one of great interest. The fact that ammonium sulphate was decomposed at moderate temperatures was not generally understood. It was known, however, that if sulphate of ammonia were put into the mixer in the manufacture of superphosphate and other artificial manures, a notable loss of ammonia occurred.

Mr. W. CROWDER agreed with Mr. Newlands' remarks, and referred to a paper published about 10 or 12 years ago in the *Chemical News*, dealing with investigations of a similar character to those of Mr. Watson Smith's.

Mr. DAVID HOWARD asked if there was the smallest proof that normal sulphate of ammonia existed in solution. It was a point on which he had grave doubts, for it invariably

behaved as an acid towards iron plant. He assumed that it was another instance of practical work differing from textbook equations.

Mr. WATSON SMITH, in reply to Mr. Newlands, said he believed that if evaporation took place in leaden pans, and an excess of acid were employed, there would be no loss of ammonia. He thought, however, that the excess of acid would need to be tolerably large, since on heating and concentrating sulphate of ammonia solutions, a considerable degree of acidity was produced by loss of ammonia. He handed round a specimen of hydrochloric acid made by the reaction of ammonium bisulphate upon ammonium chloride.

The CHAIRMAN, in proposing a vote of thanks to Mr. Watson Smith, said that the use of a very slight excess of acid would prevent loss of ammonia.

SESSION 1895-96.

Wednesday, February 5th, 8.30 p.m.—Smoking Concert at the Reform Club.

Meeting held Wednesday, January 8th, 1896.

MR. EUSTACE CAREY IN THE CHAIR.

SOME EXPERIMENTS RELATING TO THE MANUFACTURE OF CYANIDES.

BY JAMES T. CONROY, B.Sc., Ph.D.

IN the process of making ferrocyanide of potassium by fusing together potassium carbonate and iron borings with subsequent addition of animal matter, considerable losses take place, firstly, of potassium carbonate, but more especially of nitrogen. These losses make the process far from economical, and, notwithstanding the large amount of work done with a view to minimise these defects, it seems as if the efficiency of the process has practically reached its highest point.

For this reason many attempts have been made to prepare potassium cyanide otherwise than through the prussiate compound, and during the last half decade a very special impetus has been given to the study of these processes. The cause of this is the general adoption of the cyanide process in the recovery of gold from its ores, and although I cannot, unfortunately, give any figures showing the increased demand for this reagent, I think a study of the Patent Office Journal will afford some idea of the immense activity at present shown in this field.

The number of patents dealing with cyanides, ferrocyanides, and sulphocyanides, published during the years 1886 to 1895 is given in the following table:—

1886.	1887.	1888.	1889.	1890.	1891.	1892.	1893.	1894.	1895.
4	5	2	4	4	5	7	12	15	33

From a study of the specifications, we see that while the original method of manufacture is left almost entirely alone the newer methods proposed readily range themselves into two main divisions or groups. These are—

a. Methods for the direct production of cyanide, using as the source of nitrogen—

(1) the atmosphere,

(2) ammonia.

b. Methods in which sulphocyanides are prepared as intermediate products.

I propose to consider these methods in the order given, paying more particular attention to the processes falling under heading b.

The discovery that potassium cyanide could be produced directly and without the intermediate formation of ferrocyanide was made by Prof. Clark in 1837, who, on examining an efflorescence occurring near the boshes on some of the Clyde blast furnaces, which were worked with Neilson's hot blast, found it to consist chiefly of potassium cyanide.

A similar phenomenon was found to occur in the Harz, where carbon and the hot blast were used, and in 1843 Redtenbacher found it near the light hole in the furnaces at Mariazell in Styria, where it has since been produced in marketable quantities. In 1845, Bunsen and Playfair investigated the subject and found that the zone of formation was confined to the region just above the tuyères, that is, just above the point at which the air is blown in. To estimate the quantity formed they drilled a hole in this portion of the furnace and conducted the issuing gases into water. Analysis gave—

N	58.05
CO	57.43
H	3.18
CN	1.34

A gas of this composition meant in the Alfreton furnaces a daily production of 224.7 lbs. of cyanide of potash.

As a result of his work, Bunsen proposed a special blast furnace for the production of cyanide, in which coke and potash were arranged in alternate layers and heated in a strong blast—the cyanide fused as it was formed and could be run off at the bottom of the furnace.

Previous to this, in 1839, Lewis Thompson had already drawn attention to the fact that air led over a heated mixture of potash, carbon, and iron yielded cyanide, and his results were confirmed by Desfosses, and again in 1841 by Fownes and Young. Bunsen and Playfair also concluded that the cyanogen was produced from the nitrogen of the air, but this view was combated by Erdmann, Marchand, and Wöhler, who gave as their opinion that all cyanogen formed resulted from the fixed nitrogen of the coal.

Riecken then investigated the subject, and found, under conditions in which only atmospheric nitrogen was present, that cyanides were formed, and he further showed that the temperature of reaction must be sufficiently high to produce metallic potassium and that the nitrogen gas should be previously heated.

His experiments were confirmed by Delbrück.

These facts having become now firmly established, many attempts have been made to found a working process upon them, and numberless patents, all very similar to each other, have been taken out, but none have proved commercially successful. The essential feature is conducting N, or in later processes ammonia gas, over a heated mixture of coke and potash prepared in various ways (or in Mond's modification of Marguerite and Soudeval's process over barium oxide, which unites more readily with the nitrogen than the alkali metal) and the recovery of the resulting cyanide by distillation or lixiviation. The temperature of formation of the cyanide is in all cases extremely high, in fact so high as to kill the process, especially when ammonia is used, since this gas decomposes rapidly at the temperature employed.

According to Grüneberg (Eng. Pat., 1889, No. 13,697), the yield is much increased by absorbing the ammonia at a comparatively low temperature and then heating the resultant cyanate with charcoal at one much higher.

In an experiment performed by myself, 143 grms. of charcoal broken into pieces the size of peas were taken to

dryness with a concentrated solution containing 200 grms. potassium carbonate. The mixture was then filled into an iron tube and heated in a rapid current of ammonia gas at 900° — $1,000^{\circ}$ C. for six hours.

100 grms. of the raw material contained—

	Grms.
K_2CO_3	58
C.....	42

100 grms. of the product gave—

	Grms.
K_2CO_3	12.44
C (by diff.).....	44.93
KCN.....	3.74
$KCNO$	1.25
KHO.....	5.04

This analysis shows that a very appreciable quantity of cyanide and cyanate, in approximately molecular proportions, has been produced, but when it is considered that only 4 per cent. of the ammonia entering the apparatus was converted into cyanogen, and that the remainder was practically entirely lost, it becomes evident that we have here only a poor basis on which to ground a commercial industry.

Much better, but still very far from perfect, are processes, falling under this heading, in which a mixture of carbonic oxide and ammonia is led over, or through, a molten mixture of potash and carbon.

Young and Macfarlane (Eng. Pat., 1892, No. 3092) have produced, working on these lines, a cyanide containing 70 per cent. KCN. I have made some experiments on this process and on the lines proposed by these chemists, but my results were much less satisfactory than theirs, the products obtained containing only about 30 per cent. KCN.

The carbonic oxide was prepared by forcing a slow air current through a strongly heated and upright iron cylinder filled with small pieces of re-ignited wood charcoal. The resulting gas usually contained about 4 per cent. CO_2 , and after being freed from this by passing through potash solution and over lime it was led through a measured quantity (usually 200 c.c.) of concentrated ammonia solution of known strength. The mixture of carbonic oxide and nitrogen, now saturated with ammonia gas, was dried by passing over lumps of quicklime and finally through drying bottles filled with stick potash and then conducted into a curved steel tube of $1\frac{1}{2}$ inch bore, and containing just sufficient potash and carbon to form a lute in the bend. The mixture consisted at the start of about 200 grms. of caustic potash and 20 grms. of charcoal, and this was heated in the iron tube to from $1,000^{\circ}$ — $1,200^{\circ}$ C., and coarsely powdered charcoal added from time to time till the amount reached from 20—30 per cent. of the KHO present.

The temperature of reaction was sufficiently high to distil a small quantity of potassium from the mass and also to a slight extent some of the potassium cyanide formed. The mixture was well stirred from time to time, and when the experiment was completed the molten mass was poured into moulds and, when cold, well ground and tested.

The ammonia still remaining in the ammonia flask was estimated and a means thus found to determine what proportion had undergone useful change. From a series of fairly concordant experiments the following might be given:—

I.—KHO.....	200 grms.
C.....	20 grms. at start and 5 grms. at intervals of 6 hours.
Temperature.....	$1,150^{\circ}$ C.
After 24 hours the mass contained	21 per cent. KCN.
.. 30	29.6 ..
II.—Temperature of mass.....	$1,100^{\circ}$ — $1,200^{\circ}$ C.
Duration of experiment.....	5 hours.
The initial mixture contained ..	20.4 per cent. KCN.
The product mixture contained ..	34.4 per cent. KCN.
Per cent. NH_3 converted to KCN.	26

The analysis of several of the products gave the following values:—

	1.	2.	3.
KCN	22.1	18.59	29.6
K_2CO_3	66.9	74.35	71.0
KHO	1.5
C	7.7

The process possesses many drawbacks. Chief amongst these is the loss occurring in the ammonia used, of which, even under the very best conditions, only some 30—33 per cent. is converted into cyanide, the remainder, owing to dissociation, being entirely lost. Another disadvantage is that the formation of cyanide takes place very slowly, a production of 60—70 per cent. cyanide requiring about 30—36 hours (Macfarlane); this rate appears to increase with the continuation of the experiment, the rapidity of formation being much greater after a 30 per cent. cyanide was reached.

The most serious item, however, is the high temperature necessary to effect the conversion, the wear and tear of the apparatus owing to this cause being enormous and being the main cause of the ill-success of my investigation.

In their work Young and Macfarlane had employed a steel tube, and after a thirty-six hours' heating, this had become reduced to a thin shell. After several experiments, similar to those indicated above, it was replaced by one similar in size and shape but made of cast iron. After the first experiment (one of 26 hours' duration) the central, most strongly heated, portion had been converted almost entirely into the magnetic oxide, and this led me to think that the products of combustion had been entering through this part into the alkaline mass. This view seemed to be borne out by analysis of the products, which showed 60—75 per cent. K_2CO_3 , and also by direct experiment, in which a mixture of carbon monoxide and nitrogen, absolutely free from carbon dioxide before entering the heated tube (filled only with this gaseous mixture), contained a large percentage of this gas on leaving.

The chemistry of the reaction is supposed to lie in the formation of formamide from the ammonia and carbonic oxide and the subsequent splitting up of this, and absorption of the HCN formed by the molten potash. Under the conditions of experiment, I think that very little formamide is produced, although, working under suitable conditions CO and NH_3 give a good yield of this substance. The formation, to my mind, rather lies in the simultaneous action of potassium, carbonic oxide, and ammonia on each other, potassiumamide being perhaps formed as an intermediate product.

That carbonic oxide reacts with potassiumamide to form cyanide of potassium and water was pointed out, many years ago, by Beilstein and Geuther, but their results were only qualitative. I have found in a rough experiment, in which the potassiumamide was prepared in a glass tube, that carbon monoxide at a temperature of 560° — 600° C. readily converts this compound into cyanide, giving a yield of some 35 per cent. Working in iron vessels where the amide cannot be decomposed with formation of silicate, the yield would be much better, and possibly approach the theoretical value, that is, the formation of one molecule cyanide from two molecules of amide—

In carrying out Macfarlane's process it is not necessary to conduct the ammonia and carbonic oxide through the molten potash. In an experiment carried on in a covered iron crucible, the gaseous mixture was introduced by a tube at a point 1 inch above the fused mass (temp. $1,150^{\circ}$ C.), and the unabsorbed gas conducted away by an exit tube at the top of the crucible. After six hours, a product containing 7.4 per cent. of potassium cyanide was obtained; the absorption of the ammonia was not, however, so good as when Macfarlane's apparatus was employed, the conversion in two experiments amounting only to 4.5 and 3.1 per cent. respectively.

A process in which metallic sodium, previously or separately prepared, is used, has been patented by Castner (Eng. Pat., 1894, Nos. 12,218, 12,219). The molten metal is allowed to flow downwards over heated coke, whilst a stream of ammonia gas passes upwards through the mass.

The reaction proceeds at a much lower temperature than when potassium hydrate is used, and therefore the loss of potassium by volatilisation is diminished, and there is less loss due to dissociation of the ammonia.

Castner states that the whole of the alkali metal may by suitable working be recovered as cyanide; the conversion of ammonia to cyanogen is, however, not complete.

The reaction is thus represented:

The process, however, which seems to have the greatest future before it is the preparation of cyanide from sulphocyanide, which salts are now manufactured on the large scale by a modification of Gelis' process.

The thiocyanates were previously manufactured by fusing the cyanide (or ferrocyanide) with sulphur, and the total reversal of the old order of things here as well as in the preparation of cyanide from ammonia, for the manufacture of which latter compound the cyanides had been frequently proposed as a source, are points worthy of notice.

According to Gelis' process, which was worked some time on a manufacturing scale, ammonium sulphocyanide was prepared, according to the following equation, by heating together ammonia and carbon bisulphide under pressure—

From the equation it is seen that in each operation only a small percentage of the ammonia employed is converted into sulphocyanide, by far the greater part going over into ammonium sulphide.

This, at the temperature employed, exerts very great pressure, and the machinery required on this account to carry on the process was both complicated and costly.

The pressure from the various liquids likely to be present in the vessels have been determined by Mr. A. E. Wareing, by heating these at 100° C. in a strong iron cylinder fitted with a gauge. The volume of the iron vessel was 500 c.c., and in each case the quantity of liquid heated was the same, viz., 400 c.c.

All the ammoniacal solutions contained 6 per cent. of NH_3 . The following were the values obtained:—

	Lbs.
Water.....	20
$\text{Ca}(\text{SH})_2$ solution.....	25
NH_4HO ".....	40
$(\text{NH}_4)_2\text{S}$ ".....	50
NH_4HS ".....	140

It is thus seen that the value for the ammoniacal liquors is high, while that for $\text{Ca}(\text{SH})_2$ is not much higher than that of steam at atmospheric pressure, and these measurements give a good indication of the value of one of the recently introduced improvements shortly to be described.

A further difficulty in this process is the economical conversion of the sulphocyanide into cyanide.

To overcome the first of these difficulties, that caused by the sulphuretted hydrogen, several modifications of Gelis' process have been proposed, the principle of all, however, being the same, viz., the absorption of the evolved sulphuretted hydrogen by some non-volatile basic substance to cause a diminution in the pressure and to leave all the ammonia free for conversion to sulphocyanide.

The first patent was taken out in 1891 (No. 5351) by Hood and Salamon, who proposed the use of peroxide of manganese for this purpose. This they obtained, mixed with lime, by washing Weldon mud till completely free from calcium chloride, or by using the native ore (wad), or by ignition of the carbonate. A mixture of calcium and manganese sulphocyanides was thus obtained, together with sulphide of manganese and sulphur. The soluble sulphocyanides were then filtered and the contained manganese and calcium separated by fractional precipitation with

alkaline carbonate, the manganese, which possesses a greater affinity for carbonic anhydride than the calcium, coming down first.

In 1893, two patents were taken out, quite independently, for a modified process very similar to the above; the first by Crowther and Rossiter (No. 17,846) and the second by Hurter, Hetherington and others (No. 21,451); and this process, to be now described, is the most important of those yet evolved.

The above-mentioned chemists found that oxides of iron and manganese or other element to form an insoluble sulphide were not necessary to the reaction, and that lime was by itself quite sufficient to cause a rapid and complete conversion.

According to these specifications, calcium hydrate, water, ammonia, and carbon bisulphide in certain proportions are agitated in a closed, steam-jacketed iron vessel fitted with a pressure gauge, thermometer, and the necessary taps for charging and withdrawing the contents. The agitation is carried on at 100° C., and lasts for from 2—6 hours, until complete reaction has occurred.

The product, after distilling off any excess of free ammonia, is filtered from the lime, &c., and carbon dioxide is blown through the liquor in any suitable apparatus, e.g., Chance carbonators. This drives off sulphuretted hydrogen, at the same time precipitating the lime of the calcium sulphhydrate as calcium carbonate, whilst the calcium sulphocyanide remains in solution and may be utilised as desired.

I have made some experiments on the formation of sulphocyanide under varying conditions and on the subsequent conversion of this into cyanide, and the following is a record of the results obtained:—

I. Preparation from carbon bisulphide and ammonia. Carbon bisulphide and ammonia in the proportion ($\text{CS}_2 : 4\text{NH}_3$) were heated in a revolving iron cylinder for $3\frac{1}{2}$ hours at 100° C.; the product was filtered for the precipitated iron sulphide, and after the removal of the accompanying ammonium sulphide the amount of NH_4CNS formed was determined.

The yield was quantitative.

II. A mixture of calcium hydrate, carbon bisulphide, and ammonia (in the proportions $\frac{1}{2}$, 1, 3 mols. respectively) were heated together as in Experiment I. Here the lime added is just sufficient to form calcium sulphocyanide, the whole of the SH_2 liberated being absorbed by the ammonia.

Here again the yield was quantitative.

III. In Hetherington's specification we find the statement that excess of ammonia over that necessary to give the nitrogen of the CNS is required, since during the reaction calcium thiocarbonate is formed, and unless there is plenty of ammonia to decompose this compound some of the CS_2 is lost:—

This statement may be put into the form of the following question:—Supposing that some of the CaS and CS_2 combine to give CaCS_3 , can this compound react with ammonia as follows:—

or is excess of ammonia necessary to bring about the decomposition?

That excess is necessary, the following experiments, carried out by Dr. B. Zahorski and myself, show. A solution of calcium sulphhydrate was mixed with calcium hydrate and carbon bisulphide in theoretical proportion to form calcium thiocarbonate, and the mixture heated in a closed vessel under pressure, and with agitation at 60° C. On opening the vessel the whole of the carbon bisulphide was found to have disappeared and a solution of calcium thiocarbonate remained.

This was made up to a known volume, and equal parts were heated in beakers or open dishes, or under pressure in a closed cylinder with ammonium carbonate or sulphate, and varying amounts of free ammonia. The results obtained are embodied in the following table, in all cases

1 mol. CaCS_3 being treated with 1 mol. Am_2CO_3 or 1 mol. Am_2SO_4 :—

	Mols. NH_4HO added per 1 mol. CaCS_3 .	Per Cent. CaCS_3 converted to NH_4CNS .
a. $(\text{NH}_4)_2\text{CO}_3$ in open vessels	0 0 1 3 5 6 20 25	3.27 3.91 5.30 11.30 12.90 21.20 28.50 47.80
b. $(\text{NH}_4)_2\text{SO}_4$ in open vessels	0 12	5.10 27.10
c. $(\text{NH}_4)_2\text{CO}_3$ in closed vessels ...	2 12	72.10 92.95

Allowing for impurities in the carbon bisulphide, the yield of sulphocyanide was looked upon as theoretical when it reached 95 per cent. of that calculated from the weight of carbon bisulphide added.

The conversion of the ammonium sulphocyanide into the Ca and K salts was effected by boiling the solution with the calculated quantity of calcium hydrate, caustic potash, or potassium carbonate, and collecting all the evolved ammonia in acid.

The quantity of ammonia evolved was calculated and the amount of sulphocyanic acid present in the residue determined.

The following results were obtained—

NH_4CNS in Still calculated to KCNS .	Ca or KCNS found, calculated to KCNS .	NH_3 Theoretically Recoverable.	NH_3 Recovered.
18.31	18.24	3.21	3.05
2.187	2.173	1.22	1.23
"	2.178	"	1.23
"	2.192	"	1.21
"	2.211	"	1.13
"	2.182	"	1.22

From these experiments the following conclusions may be drawn :—

1. The reaction between carbon bisulphide and ammonia to form sulphocyanide proceeds easily and completely. The addition of lime does not influence the yield in one way or the other, provided that ammonia is present in excess, but simply serves to reduce the pressure within the apparatus.

2. Carbon bisulphide and calcium sulphide combine quantitatively in theoretical quantities, when treated under suitable conditions, to form the soluble calcium thiocarbonate. This combination takes place in the cold or at 100°C ., but especially well at 50° — 60°C .

3. The solution of calcium thiocarbonate may be quantitatively converted, under suitable conditions, into sulphocyanide. For a good yield there must be a large excess of ammonia present and the reaction must be performed under pressure.

In later specifications it has been proposed to replace a portion of the lime by magnesium hydrate, which, under pressure, absorbs the SH_2 , but on releasing the pressure, evolves the gas below 100°C ., the $\text{Mg}(\text{OH})_2$ being reprecipitated ready for use.

Conversion of Sulphocyanide to Cyanide.

The conversion of sulphocyanide to cyanide is, as inspection of the formulae at once shows brought about by the withdrawal of one atom of sulphur from the former compound. This change may be accomplished either by reduction or by oxidation; in the first case the sulphur is withdrawn by means of some suitable metal, and in the second case it is oxidised to sulphuric acid. This oxidation of the sulphur of sulphocyanides to sulphuric acid and

the simultaneous formation of hydrocyanic acid was first observed by Erlenmeyer, who proposed titration with permanganate of potash as a method of determining sulphocyanides. The reaction which must be carried out in acid solution proceeds thus :—

Parker (Eng. Pat., 1888, No. 17,417, and 1889, No. 2383) found that a similar oxidation occurred on electrolysis, and he patented a process in which a current is driven through a solution of pure hydrocyanic acid or one of a soluble sulphocyanide in sulphuric acid solution. The HCN gas evolved must be collected and absorbed in alkali or utilised in other ways; a sulphate remains in solution.

Naturally such a process as this, in which large quantities of a poisonous gas have to be dealt with, is not very pleasant to work, and a simple removal of the sulphur by some metal with the direct formation of potassium cyanide is much more desirable.

Playfair (this Journal, 1892, p. 14) has investigated this subject and published the results he obtained.

In the first experiment he tried heating the sulphocyanide in a current of hydrogen or hydrocarbon gas, hoping by this means to remove the sulphur as SH_2 or CS_2 and to leave a residue of pure cyanide behind.

With hydrogen gas he found that 80 per cent. of the sulphocyanide was decomposed, but not altogether in the desired direction. The reaction which he found to occur was :—

i.e., by this method only half of the sulphocyanide, at the most, can be recovered as cyanide, and this 1, also, have found to be the case. With hydrocarbon vapours SH_2 was evolved as with hydrogen, but no trace of cyanide could be found in the product.

Playfair next tried reducing with carbon at a red heat; here a small amount of conversion occurred, but not sufficient to give any practical results.

He, therefore, next turned his attention to metals, and with these obtained much more satisfactory yields, and he has patented a process (1890, No. 7764) in which lead or zinc, separately or mixed together, are used.

He states in the Society's Journal that he has obtained with zinc an average yield of 70 per cent.; with lead the reduction is more difficult to effect, whilst with copper, tin, &c., only poor results are obtained.

I have examined the reduction of potassium sulphocyanide by means of lead and zinc by heating quantities, ranging from 40—100 grms., of potassium sulphocyanide with granulated zinc and lead scrapings respectively. The sulphocyanide was contained in a porcelain dish and the metal stirred well in, the temperature being about 400°C . As the reaction proceeded the insoluble metallic sulphide was seen to gradually form and separate out from the mass, but the reduction was a very gradual process, especially in the case of the lead, owing to the fused heavy metal sinking to the bottom of the containing vessel and thus preventing an efficient stirring being carried on.

In all cases from 70—80 per cent. of the sulphocyanide reacted upon was converted into potassium cyanide, but, working with the metals and KCNS in equivalent proportions, after 30 minutes' heating less than 10 per cent. of the sulphocyanide present had been reacted upon. To increase the rapidity of the decomposition it was sought to effect a more intimate mixture of the reacting materials. This could be done either by means of a more perfect mixing arrangement or by employing the metal in a very finely divided state. This latter method was adopted as being the more convenient of the two, and a number of experiments using zinc dust were made.

The zinc dust and sulphocyanide were well ground and mixed together and then heated cautiously in a crucible. The mass became pasty and frothed, and after a short time began to harden at the bottom of the crucible. When this stage was reached the source of heat was removed, and, maintaining a constant stirring, the reaction was allowed to extend to the rest of the mass, which became suddenly red hot and perfectly solid. The resulting product was in

all cases porous and capable of easy lixiviation. The yields varied with the amount of zinc used, and employing only the calculated quantity of zinc the reaction did not proceed quantitatively, as the following table shows:—

Theoretically 40 grms. KCNS require 25·8 grms. zinc for complete conversion.

KCNS.	Zinc Dust.	Per Cent. KCNS Converted to KCN.	Per Cent. KCN in Lixivated and Dried Product.
40	27	50·5	..
40	30	54·0	..
100	100	59·8	13·76
20	20	60·6	6·8
30	25	68·9	15·5

The poorer conversion obtained by using zinc dust compared with that from the granulated zinc is due to impurities in the dust, and also to the fact that some of the dust became oxidised before entering into the reaction with the sulphocyanide. Working in a reducing atmosphere would probably improve the results. In nearly all cases some sulphocyanide remained unattacked, and most of the preparations contained a fair proportion of cyanate.

When zinc and copper were used some of the metal went into solution in the form of a double cyanide; in some cases, when a large excess of zinc had been used, colourless crystals of $\text{Zn}(\text{CN})_2$, 2KCN would separate out from the liquors on standing.

It is practically impossible to remove the zinc completely from the finished product without causing a considerable loss of cyanide or introducing some other impurity, and it will be a matter of extreme difficulty, using this metal, to obtain a perfectly pure product.

With copper and sodium lead alloy a moderate decomposition was obtained; the products were, however, far from pure. In the one case, much copper had formed compounds soluble in water, and in the second, sodium sulphide was produced. Antimony and bismuth seem to be practically without action on the sulphocyanide.

The product obtained by lixiviating the raw cyanides obtained as above and evaporating to dryness the solution so obtained, gave a cyanide containing about 50 per cent. KCN. The solutions evaporated were at the start not pure, containing carbonate, cyanate, &c., and these salts possibly aided the decomposition of the cyanide, the loss of which, during the evaporating process, varied from 3 to 15 per cent.

This shows that a serious loss must be looked for here unless special precautions are taken. Playfair states that this loss may be entirely avoided by evaporating the solutions in a good vacuum, and it is better to have them as concentrated as possible at the start. It is also important to have no large excess of free alkali present, otherwise brown insoluble decomposition products are formed.

From Crowther and Rossiter's specification (Eng. Pat., 1891, No. 8365), it appears that it is necessary to have the sulphocyanide absolutely dry before treatment with the metal, and that simply heating the salt above its melting point is not sufficient, but that a current of some dry, indifferent gas, *e.g.*, nitrogen or carbon dioxide, must be blown for some time through the fused salt.

To obtain a cyanide free from zinc and products due to secondary decompositions formed on fusion with zinc, it has been attempted to convert the sulphocyanide into ferrocyanide, from which compound, either by simple heating or by fusion with metallic sodium or sodium lead alloy, a cyanide of fine quality is readily obtained.

Experience has taught that for a good reaction to take place between iron and sulphocyanides the following conditions must be observed:—

- (1.) The materials must be perfectly dry.
- (2.) The iron must be very finely divided.
- (3.) The substances must be intimately mixed.
- (4.) A reducing atmosphere should be maintained around the reacting mass.

Iron Powder.—This was prepared by well mixing 200 grms. of oxide of iron with 100 grms. of pitch, and heating

the mixture in a crucible for three hours at a temperature of over 1,000° C. The resulting mass, which contained 83 per cent. of its iron in the metallic form, was ground with a second 50 grms. of pitch and then heated as before for a further three hours. The iron present in the product of this second heating was wholly metallic.

The total iron was estimated by ordinary methods, and that present in the metallic condition was determined by titration of the ferrous sulphate liberated by addition of the powder to copper sulphate solution.

Formation of Ferrocyanide (Eng. Pat., 1893, No. 21,451).—20 grms. KCNS, 26 grms. Fe powder (60 per cent. Fe, 40 per cent. C.) 8 grms. pitch to prevent oxidation occurring, were well mixed and heated to about 400° C. for half an hour, being well stirred the whole time. The mixture on warming gave at first a thick fluid which became, on continuing the heating, gradually dry and solid. The reaction was discontinued when this stage was reached and the product tested for K_4FeCy_6 and KCNS.

K_4FeCy_6 formed 15·36 grms.	76·8
KCNS recoverable 3·64 grms.	18·2
Loss	5·0

In a second experiment, performed as nearly as possible under the same conditions, the yield of ferrocyanide was much less, amounting only to 48 per cent.; 40 per cent. of the sulphocyanide remained however in this case unattacked.

Calculated on the amounts of sulphocyanide decomposed the quantities converted to ferrocyanides were 93·9 per cent. and 80 per cent. in the respective experiments.

On heating the second product further, in the hope of increasing the yield, it was found that the whole of the sulphocyanide disappeared without any formation of ferrocyanide occurring; in fact the quantity of this substance present had diminished.

In an experiment in which the upper and lower portions of the product were analysed separately it was found that for every 100 parts KCNS originally present in the lower solid portion, 64·2 had been converted to ferrocyanide and 28·4 remained unchanged; and that in the upper, more granular part, only 26·5 had been converted to ferrocyanide, whilst 51·6 remained unchanged.

An attempt to convert the sulphocyanide into ferrocyanide by heating a concentrated aqueous solution with iron wire and the iron used in the foregoing experiments in a sealed tube entirely failed, no decomposition whatever occurring.

These experiments, and others, indicate that although a good conversion may occur under suitable conditions, the reaction proceeds very irregularly, and that its end point is difficult to determine—a too long continuation of the heating results in changes opposite to those desired.

A short account of the analytical methods employed might be of interest, one or two of the observations noted here being, I think, new.

It is to be understood that in all cases sulphides, if present, were removed by means of lead carbonate before the testing for cyanogen compounds was proceeded with.

KCN.—This was estimated in the usual way by titration with iodine in neutral solution or by decinormal silver nitrate in alkaline liquids.

In a paper recently published by Clennell (Chem. News, 72, 227), mention is made of the interfering action of ferrocyanides, &c. in the determination of potassium cyanide. His experience is borne out by my own experiments, and the error introduced seems to vary with the percentage of admixed ferrocyanide. It makes no difference whether the ferrocyanide is present at the beginning of the titration or whether it is only added after the milkiness in an ordinary cyanide titration has been reached; in this latter case the milkiness disappears on the addition of ferrocyanide and returns when more silver solution has been added. The magnitude of the error may be judged by the following titrations:—

25 c.c. KCN solution (5·25 grms. per litre) required to milkiness.	10·53 c.c. $\frac{N}{10}$ AgNO_3
25 c.c. KCN solution + 5 c.c. K_4FeCy_6 (10 grms. per litre) required to milkiness.	10·55 ..

25 c.c. KCN solution + 5 c.c. K_4FeCy_6 (10 grms. per litre) required to milkyness.....	10.55 c.c. $\frac{n}{10}$ $AgNO_3$
25 c.c. KCN solution + 10 c.c. K_4FeCy_6 (10 grms. per litre) required to milkyness.....	10.73 "
25 c.c. KCN solution + 10 c.c. K_4FeCy_6 (10 grms. per litre) required to milkyness.....	10.75 "

KCNS.—The method employed here was to add nitric acid and a little ferric sulphate solution, and to then titrate with silver nitrate solution until the red colour due to ferric thiocyanate vanished. The nitric acid must be free from the lower nitrogen oxides, which rapidly destroy the sulphocyanides, and the ferric chloride solution free from chlorides, which interfere with the reaction.

The colour change is sharp. Soluble ferrocyanides interfere with the precipitation of sulphocyanides by means of silver nitrate, and it is therefore important to precipitate them completely before titration, and when much Prussian blue is present the solution should be filtered.

Experiment has shown that silver sulphocyanide is precipitated before silver cyanide in acid solutions, whilst the reverse is the case when the solution is alkaline. It is thus possible by two silver titrations to find the amounts of these substances present in any sample. This may even be done in one portion of the solution, when the —CNS present is more than half the —CN. In this case the slightly alkaline solution is titrated to milkyness with $AgNO_3$ and is then acidified, and the titration continued, after the addition of ferric sulphate, with good stirring till the red colour vanishes.

25 c.c. KCNS solution required	11.20 c.c. $AgNO_3 \frac{n}{10}$
25 c.c. KCNS solution + 10 c.c. KCN solution required	11.85 "
25 c.c. KCNS solution + 10 c.c. KCN solution required	11.95 "
25 c.c. KCNS solution + 25 c.c. KCN solution required	11.95 "
25 c.c. KCNS solution + 25 c.c. KCN solution required	11.90 "

when the solution had been made acid at the start; when not made acid until after the KCN had been determined the readings were 11.8 and 11.9 c.c.

In a mixture containing KCN, KCNO, KCNS, and K_4FeCy_6 it was found possible to obtain rapidly satisfactory results (approximately, but not quite, accurate) by the following procedure:—

- (1.) Titration with silver nitrate to milkyness (KCN).
- (2.) Addition of potassium chromate (after neutralisation of the solution) and continuation of the silver titration to completion (KCN, KCNO, KCNS, K_4FeCy_6).
- (3.) Titration with potassium permanganate ($\frac{N}{2}$) in acid solution (KCNS + K_4FeCy_6).
- (4.) Determination of K_4FeCy_6 by precipitation as Prussian blue, and estimation of this in the usual way with potassium permanganate.

In conclusion, I wish to express my sincere thanks to Dr. Hurter for help in many ways, and kindness in placing certain of the results here given at my disposal, and also to the directors of the United Alkali Company, in whose laboratory the above work was carried out, for permission to read this paper.

CONTRIBUTIONS TO THE ANALYSIS OF FATS.

V.—THE DETERMINATION OF UNSAPONIFIABLE MATTER.

BY DR. J. LEWKOWITZCH.

THE determination of the unsaponifiable matter in fats and oils appears to be very easy and the directions given in text-books seem to be simplicity itself. I have elsewhere (Chemical Analysis of Oils, Fats, and Waxes, &c., pp. 171, 172) compiled the most important methods under two heads, viz. (a) Extraction of the soap solution with ether or petroleum ether; and (b) Extraction of the dry soap with solvents. There are, however, cases in which the choice of the solvent is not a matter of indifference, and where it is necessary to use circumspection instead of trusting blindly to text-books. Such a case presented itself to me in the examination of a sample of shark liver oil and of some kinds of whale oil.

When using petroleum ether (carefully fractionated so as to exclude all portions boiling above $80^{\circ}C$.) for the extraction of the unsaponifiable matter, it was found that large quantities of soap were dissolved, so large, indeed, that the petroleum ether could not be distilled off easily on account of the violent frothing of the solution. It was, therefore, necessary to remove the dissolved soap by washing the petroleum ether with dilute alcohol (50 per cent.) before the amount of the unsaponifiable matter could be determined.

The results obtained with petroleum ether were very striking indeed; they were very capricious and differed enormously from those obtained by means of common ether. Whereas the latter solvent gave invariably about 10 per cent. of unsaponifiable matter, the petroleum ether yielded results varying from 1.38 to 3.73 per cent.

The second of the above-mentioned methods, viz., extraction of the dry soap with solvents, was then resorted to, but with no better result; large proportions were dissolved by the petroleum ether and had to be washed away by means of dilute alcohol.

No doubt this peculiar behaviour of the shark liver and whale oils is due to the nature of the unsaponifiable matter, which would naturally be assumed to consist of the aliphatic alcohol derived from the spermaceti dissolved in these marine animal oils. Evidently the alcohol is sparingly soluble in petroleum ether, and on treating the saponified oil with that solvent large proportions of soap are dissolved simultaneously with the unsaponifiable matter.

The same difficulty has been experienced by Allen in the case of beeswax, carnauba wax, and other substances

containing myricyl alcohol, which is but sparingly soluble in the cold solvent, and he recommends in such cases to neutralise the saponified mass exactly with acetic acid, using phenolphthalein as an indicator, and to precipitate with lead acetate. The precipitate is then washed, dried, mixed with sand, and boiled out repeatedly with petroleum ether.

I intend investigating more closely the cause of the peculiar behaviour of marine animal oils mentioned above, and have instituted two series of experiments comprising (1) the examination of mixtures of olive oil (and similar oils as regards the proportion of unsaponifiable matter) with varying proportions of spermaceti; and (2) the isolation of the unsaponifiable matter from shark liver oil and study of its solubility in the solvents employed usually.

It will be clear from the foregoing remarks that it is the safest to employ common ether for extraction, and the fear of continental chemists lest the results may be vitiated by dissolved soap can be easily allayed by using the precaution I have recommended some time ago, viz., to incinerate the unsaponifiable matter and determine the alkalinity of the residue, if any should be left.

In conclusion, it may be useful to point out, at the hand of a practical example, the pitfalls open to the analyst if due caution be not exercised. Suppose the shark liver oil has been saponified in the usual manner—giving the correct saponification value—and exhausted with petroleum ether: the amount of unsaponifiable matter will be found far too low, say, 1 per cent.

On acidulating the exhausted soap solution with a mineral acid, there would separate an oily layer supposed to consist of fatty acids. By weighing these, one would obtain, say, 96 per cent. So far everything would appear simple. On further examining the fatty acids, one would obtain an acid value leading to a very high molecular weight, and it would be but natural to draw the inference that the oil under examination contains fatty acids of abnormally high molecular weight. The true explanation, however, is that the separated oily layer consisted of a mixture of fatty acids and that portion of unsaponifiable matter which had not been extracted by the petroleum ether. The acid value would consequently be wrong, and all conclusions drawn from the wrong premises valueless.

CONTRIBUTIONS TO THE ANALYSIS OF FATS. VI.—WOOL-WAX.

BY DR. J. LEWKOWITZ.

SEVERAL years ago I published an inquiry into the constitution of wool-fat (Yorkshire grease), the nature of which had not been known till then in such completeness as to assign to wool-fat the place it should occupy in a natural classification of fatty substances. The results of that inquiry led unmistakably to the conclusion that that portion of natural wool-fat which I then termed neutral fat is a true wax in the strict sense this generic term implies. Natural wool-fat resembles beeswax, its closest relative, in that it contains a considerable proportion of free fatty acids and a small amount of free alcohols, besides true waxes, and the term "wool-wax" should therefore be substituted for "wool-fat." But, considering the fact that the waxy matter obtained from wool by extraction with volatile solvents contains notable proportions of potassium salts of fatty acids, and, further, considering that the commercial wool-fat is, as a rule, contaminated with fatty acids derived from the soap used in scouring the wool, it is more convenient to retain the term "wool-fat" for the commercial product. I propose, therefore, that the name "wool-wax" be given to the neutral portion of the wool-fat. This neutral portion consists of a mixture of a true wax and free alcohols, the former predominating considerably. The name "wool-wax" appears to me all the more desirable as this neutral portion of wool-fat is now obtainable in commerce in large quantities, both in the anhydrous and hydrated state (comp. Chemical Analysis of Oils, Fats, and Waxes, &c., p. 584), and confusion with the crude wool-fat is thereby avoided. Of course, it must be borne in mind that the various commercial preparations need not be

necessarily of uniform composition. In fact, wool-waxes of different origin vary within certain limits, much as other natural products do.

I have undertaken the examination of "wool-wax" with a view to elucidating the nature of its constituents, and although the results detailed below are very far from being complete, still I publish the results obtained hitherto, as I may not be able to conclude this work within the near future.

The wool-wax was dehydrated by melting and allowing the water to subside. The anhydrous wax was then dissolved in absolute alcohol and saponified by means of metallic sodium in a flask attached to an inverted condenser. The alcohol was distilled off and the mixture of soap and alcohols, whilst still warm, poured into water, with which it was shaken up until the temperature had fallen so that common ether could be added with safety. After vigorous shaking the mixture was allowed to stand for some days. It then separated into three layers, viz.:—

(1.) Ethereal layer on the top, consisting of the ethereal solution of the alcohols—unsaponifiable matter.

(2.) An aqueous layer on the bottom, being a solution of soap.

(3.) An intermediate thick layer, representing a soap sparingly soluble in water.

The ethereal layer was drawn off, washed well with water (which was later on added to 2 and 3), and the mixture of 2 and 3 exhausted with ether until no more unsaponifiable matter was extracted. Each portion was examined for soap. The first extractions yielded the unsaponifiable matter free from soap; later on, small quantities of soap appeared in the extracts, increasing in inverse proportion to the quantity of unsaponifiable matter. These were treated separately with warm water until free from ash before being united with the main portion.

Thus the alcohols—unsaponifiable matter—were obtained free from ash.

1. *Unsaponifiable Matter*.—The amount of unsaponifiable matter obtained was 51.84 per cent. It represented a very mucous substance of light yellow colour. The following constants were ascertained:—

Melting-point	46°–48° C.
Iodine number	26.35
Increase in weight on boiling with acetic anhydride	5.26 per cent.
Saponification value of the acetate	153.23

From the table given by me in this Journal, 1892, 138, and reproduced here—

	Increase on Boiling with Acetic Anhydride. Per Cent.
Cetylalcohol	17.2
Cerylalcohol	10.6
Cholesterol (or ischolesterol)	11.3

it will be seen that cetylalcohol must be almost absent. Further, we may conclude from the low iodine number that the proportion of the two cholesterol cannot be very large, the iodine value of cholesterol being 67.7 (this Journal, 1892, 143).

A method of separating aliphatic alcohols from the cholesterol seemed to be afforded by the behaviour of the former with soda-lime, when the alcohols are converted into the corresponding fatty acids. A few crucial experiments with sperm oil and pure cholesterol decided in favour of this method. On heating the sperm oil alcohols with soda-lime, the bulk of the alcohols were converted into fatty acids, only 4–6 per cent. of unsaponifiable (unchanged alcohol) being recovered. The crude fatty acid had the melting-point 38°–40° C., and the acid value 181.7.

On the other hand, pure cholesterol on being treated in the same manner gave 93 per cent. of unchanged cholesterol, even when the temperature was kept for two hours at 280° C. Only traces of an acid substance were obtained.

On subjecting the wool-wax alcohols to the soda-lime treatment, maintaining the temperature at 250° C., about 80 per cent. were recovered as unchanged alcohols and 6 per cent. of fatty acids, of the melting-point 51°–53° C., isolated from the soap solution.

I intend to treat larger quantities of the wool-wax alcohols in this manner, and to further study the nature of its components. It may be pointed out here that Marchetti has recently detected the presence of a new alcohol—lanolinalcohol, $(C_{12}H_{24}O)$ —in the unsaponifiable portion of wool-wax. The amount of this new alcohol in the mixture of the alcohols is stated to be 1 per cent.

2. *Fatty Acids of the Easily Soluble Soap.*—The separation of the easily-soluble soap from the solid soap, 3, was effected by filtration.

The soap solution was freed from the dissolved ether by distilling it off, and the fatty acids were then isolated in the usual manner by boiling. The amount obtained was 25.5 per cent. The colour of these acids was light reddish-brown.

The following constants were determined:—

Melting-point.....	52°5'—56°5' C.
Iodine value.....	9.95
Acid value.....	173.88
Saponification value.....	189.67
Ether value.....	15.79

The definite ether value points to the presence of lactones, as I have shown before (this Journal, 1892, 137).

A series of experiments was carried out to determine the degree of dehydration that takes place with increase of temperature; at the same time the change in the iodine value was ascertained. The results obtained hitherto merely show that above 120° C. the acids rapidly lose water, whereas the iodine value varies but little.

It then occurred to me that dehydration might take place the very moment the fatty acids were isolated by boiling the soap solution with mineral acid. Therefore, in another preparation of substance the ether was not removed by distillation but mineral acid was added to the cold solution and more ether added, so that the separated fatty matter was at once transferred to the ether, from which it could be recovered at a low temperature. The fatty matter thus obtained was *white* and gave the following constants:—

Iodine value.....	10.1
Acid value.....	168.22
Saponification value.....	192.82
Ether value.....	25.9

The ether value is in this case larger than before, and it thus becomes evident, that whereas the iodine value remained practically constant, on heating the acids with water—as it happens on liberating them from the solution on boiling—the lactones are partially converted into fatty acids.

There is no doubt that lactones are present, and the next step was to isolate the lactones. This was done by carefully neutralising the fatty matter with aqueous potash and exhausting the soap solution with petroleum ether. The fatty acids were liberated from the soap solution in the usual manner; if the separation of lactones from fatty acids was complete, the acid and saponification values of the acids should be identical. I actually found—

Acid value.....	194
Saponification value.....	193

The examination of the lactones led to the following constants:—

Iodine value.....	2.4
Acid value.....	1.5
Saponification value.....	174.63

It was therefore practically free from free fatty acids. The soap solution obtained from the lactones (anhydrides) by boiling with alcoholic potash was treated with a mineral acid to separate the fatty acid. The determination of the acid value of the latter was to show whether the lactones had been re-formed. The acid value of the substance was found 61.24, thus proving that lactones had been re-formed to a considerable extent.

3. *Fatty Acids of the Sparingly Soluble Soap.*—The fatty acids were at first liberated by boiling. They gave the following constants:—

Iodine value.....	6.95
Acid value.....	166.5
Saponification value.....	128.2
Ether value.....	21.7

In a second preparation the fatty acids were liberated in the cold in the same manner as described above. The isolated fatty matter is but sparingly soluble in cold ether or petroleum ether, and large quantities of the solvent had to be used to effect complete solution. The fatty substance thus obtained was white; its quantity was almost equal to that of the fatty acids from 2, amounting to 26 per cent. On examination, the following constants were obtained:—

Iodine value.....	3.9
Acid value.....	86.16
Saponification value.....	135.86
Ether value.....	49.70

This portion of the wool-wax contains therefore a larger amount of lactones than that dealt with under 2.

The fatty substance was then separated, in the manner described above, into (a) fatty acids, and (b) lactones.

The fatty acids (a) gave the following constants:—

Iodine value.....	1.85
Acid value.....	131.38
Saponification value.....	141.8
Melting-point.....	65°—66° C.

It will thus be seen that either the separation had not been complete, or, what is more likely, judging from some experiments, that further formation of lactones had occurred on decomposing the soap.

The lactones (b) had the following constants:—

Iodine value.....	8.69
Saponification value.....	115.0

On separating the fatty matter from the alcoholic soap solution by acidulating with a mineral acid, lactones were re-formed to a varying extent in various experiments; but this much was established with certainty, that the re-formation of lactones in this portion of the wool-wax took place to a very much smaller extent than in the corresponding portion of 2.

It would be premature to draw any conclusions from these incomplete experiments, which I publish here but with reluctance. However, some useful purpose may be served if I have succeeded in showing that the composition of wool-wax represents perhaps the most interesting amongst the many unsolved problems in the chemistry of fats and waxes.

Meeting held on Friday, January 3rd, 1896.

MR. GEORGE E. DAVIS IN THE CHAIR.

ON SOME NEW METHODS OF TESTING INDIGO.

BY DR. B. W. GERLAND.

THE number of methods described for analysing indigo is considerable; but of all these not one is known which is reliable, and the only way left to arrive at an approximate valuation is swatch dyeing. This is all the more surprising in consideration of the great value of indigo as a commercial article. The analytical method most relied on is the reduction process, and weighing of the recovered indigotine, although it has been repeatedly shown that part of the indigotine is lost; and recently I have convinced myself that the indigotine recovered and weighed in this process is impure. Some time ago I was anxious to ascertain the precise amount of indigotine on a piece of calico, and followed most carefully the rules given for this method, but obtained very inconsistent results. Moreover, the indigotine obtained was very impure, in fact, to such an extent that it could not be titrated by hydrosulphite by the Berthsen-Müller process. With similar results I applied the reduction process to commercial indigo. In conversation with

several chemists who are chiefly engaged in indigo testing, I stated these facts, but found that their implicit faith in this method remained unshaken. Through the courtesy of some of them I obtained samples of the indigotine weighed, and found these to be as impure as my own preparations. It is not impossible that by some lucky chance this method may occasionally give correct results as loss and gain may compensate.

These experiences induced me to endeavour to find a more reliable process, and I directed my attention to the well-known property of indigotine to enter into solution with several carbon compounds at high temperatures, and to crystallise on cooling.

Of all these solvents tried nitrobenzol appeared to be in all respects the most suitable. The article prepared on the large scale is of great purity, certainly pure enough for this purpose. The early trials yielded crystals, but they took several days for extraction and were not therefore very encouraging. By degrees, however, the apparatus was perfected and simplified, and with this I can now effect the complete extraction in from half an hour to one hour.

The apparatus consists of a large test tube 10 mm. diameter and 15 to 20 cm. long, clamped in a retort stand above a burner; a glass tube of 7 to 8 mm. inside diameter and about 50 cm. long serves as a reflux condenser. Its lower end is ground off obliquely, and has glass knobs fused to it to secure the wire hook, on which is suspended the filtering tube. This tube is formed of thin glass tubing about 20 mm. diameter, and 4 to 4.5 cm. long, both ends slightly belled out. Over the lower one a piece of fine calico is wired, upon which a few drops of fine paper pulp are placed, this, after drying, forming a serviceable filter. The cloth is protected against the squirts of the boiling nitrobenzol by a small shield, such as the lid of a porcelain crucible. The upper end is tied with thin wire, which allows it to be connected to the hook of the condensing tube. The latter passes through a glass funnel, whose tail has been cut off, resting on the top of the test tube. The condensing tube is held in a central position to the test tube by means of a cork, through which it passes loosely, so as to allow it to slide up and down, and which is held in a clamp. Lastly, the condensing tube is connected with an aspirator drawing a gentle current of air during the operation.

The ground sample of indigo is weighed into the filtering tube, this is hooked to the condensing tube, and the latter fastened in its position centrally to the large test tube, so that the filter is about 6 cm. above the bottom of the test tube. The latter is charged with about 25 c.c. of nitrobenzol, the lamp is lighted, and the aspirator set to work. The function of the latter is highly essential. It draws the vapours of the boiling nitrobenzol, which, without it, would condense on the sides of the test tube and escape between its mouth and the covering funnel, and conveys the condensed liquor into the filtering tube. It also carries off the steam from the water, which otherwise would condense and fall into the filter tube, causing explosions. By a careful regulation of the aspirator and the heat no nitrobenzol vapours escape into the room, and the test tube is fully supplied with condensed liquor. The vapours of the nitrobenzol do not rise in the tube above 20 cm. With 0.5 gm. of indigo and 25 c.c. of nitrobenzol the extraction requires from one half to one hour, during which time the aspirator discharges about 2 litres of water. Crystals separate at an early stage, but with regular boiling the operation is not interfered with by bumping. When the droppings from the filter tube are colourless the extraction is complete: the lamp is removed and the apparatus cooled and dismantled.

The indigotine has separated in beautiful crystals in a deeply coloured liquor, and only a very small portion remains in solution. To save the trouble of recovering this I use the nitrobenzol saturated with indigotine in the cold. The liquor is passed through an extracted weighed filter, washed with benzol and dried. The beautiful appearance of the indigotine thus separated is deceptive. It still contains impurity amounting to from 3 to 6 per cent., and is not fit to be tested by the Bernthsen method, owing to the deep colouration. A prolonged treatment with hydro-

chloric acid, or, better still, hydrochloric acid and hydrogen peroxide, leaves it in a pure state fit for weighing or testing with hydrosulphite. The indirubine being slightly more soluble in cold nitrobenzol than indigotine it is to be apprehended that a small loss cannot be avoided in the simple manner as was done for indigotine. This loss may possibly amount to 0.1 or 0.2 per cent. on the colouring matters.

With this slight exception the method is thoroughly reliable and trustworthy and is applicable to all classes of indigo.

Estimation of Indigotine by the Monosulphonic Acid Method.

Endeavouring to have a method free from the objection just mentioned I have turned my attention to the phenicic acid and its property of being insoluble in dilute sulphuric acid. In the literature accessible to me, no statement is made about any process according to which the whole of the indigotine can be entirely transformed into the monosulphonic acid, nor any about the effect of weaker sulphuric acid on indigotine. I have ascertained that by acting with vitriol of a certain strength, and at a certain temperature, on indigo, the whole of the indigotine is converted into monosulphonic acid, so that by dilution with water the whole of the indigo is separated and the filtered liquor is colourless or pale yellow. It is necessary to observe carefully a certain relation between strength of sulphuric acid and temperature. For 0.5 gm. of indigo I use 40 c.c. sulphuric acid of specific gravity 1.67 and digest under repeated shaking for an hour in the boiling water bath. The large excess of sulphuric acid assists the subsequent filtration over the sand filter, which, with less sulphuric acid, would require to be steam-jacketed. Filtration is easily accomplished on the vacuum filter, and washing of the latter is performed with acids of the same strength heated to 100°. With proper manipulation the exhaustion of the filter is accomplished with about 40 c.c. more of the acid when the washings have become colourless. If an acid of greater specific gravity than 1.67 is used, for instance 1.7 sp. gr., digestion has to take place at a temperature of about 80°, as in the boiling water bath soluble sulphonic indigo acid would be formed. If an acid of less specific gravity than 1.67 is used the difficulties of filtration are increased. The filtrate is mixed with twice or thrice its volume of water and filtered. This filtrate is pale yellow, or with indigo prepared, as subsequently described, quite colourless, without a trace of blue in it. The monosulphonic acid remaining on the filter is washed with water containing 20 per cent. of sulphur trioxide. Boiling water dissolves this indigo sulphonic acid only partially, leaving a small amount of indigo or indigotine compound undissolved. For this reason I prefer to carry out this operation on a sand filter, dry the whole in an oven, add strong sulphuric acid, digest at about 100° for some time and remove the indigo, which is now entirely changed into the indigo disulphonic acid, from the filter by water. An aliquot part of the filtrate is then submitted to titration. My hope of being able to estimate the indigotine corresponding to the sulphonic acid by the hydrosulphite method was not realised; the neutralised solution of the sulpho acid took such a dark colour that the point at which the blue disappeared could not be sharply ascertained. It is surprising how, probably, the same impurity of commercial indigo sticks to the indigotine and its compounds when treated by the reduction method, the nitrobenzol extraction method just described, and this monosulphonic acid method. Thus Bernthsen's (August Bernthsen, *Berichte* XLII., 2277) titration of indigotine with hydrosulphite, one of the sharpest volumetric methods, is made unavailable for commercial indigos unless they have been previously submitted to an elaborate and troublesome purification. I leave it at present an open question whether the substance separated by this process is the phenicic acid of Berzelius or a new acid. I hope to finish the examination of it shortly.

So far the readiest way that I have been able to find for overcoming this difficulty has been treating the sample of raw indigo with hydrogen peroxide and hydrochloric acid, digesting some time in cold, boiling, filtering, and washing well with boiling water or weak soda solution.

After the drying of the sample thus prepared, the described treatment with weak sulphuric acid yields the sulphonic acid sufficiently pure to give good results with the Berthsen titration method. The apparatus I have used for this titration is very similar to that described by Fiemann and Preuss (Berichte XII., 1768) for the estimation of oxygen in water, and adopted by Berthsen for the titration of indigotine. It consists of:—

1. The laboratory vessel—a Woulff's bottle with three necks, of 300 to 500 c.c. capacity, standing in a white vessel with water kept at 45° to 50°. The corks are perforated for six tubes, the entrance tube for the gas free from oxygen, cut off level with the cork, the exit tube for the gas, the syphon-tube reaching to the bottom of the bottle for emptying the liquor, the tube of a tapped funnel and two tubes for two burettes.

2. Two burettes connected with the latter tubes by means of long india-rubber tubing to allow shaking of the bottle. One is charged with indigo solution, the other is for the hydrosulphite.

3. The store bottle, which I choose of large size—two litres—to minimise the effect of a possible remnant of oxygen in the gas. It communicates with the lower end of the burette by means of a glass tube and india-rubber with pinch-cock, and is placed sufficiently high to fill the same.

4. A store bottle for boiled water kept at about 45° to 50°.

Illuminating gas passed through a column of pumice charged with ferrous hydrate (amalgamated aluminium would probably be more convenient) is divided into three branches, one for the laboratory vessel, one for the hydrosulphite burette and store vessel, and the third for the boiled water store vessel. All the gas exits dip 1 to 2 cm. under water, so that these parts of the apparatus are constantly kept under that pressure.

To begin operations the laboratory vessel and hydrosulphite burette are filled with gas free from oxygen. The store vessel is filled with the hydrosulphite solution and shaken. The burette is repeatedly filled and emptied into the laboratory vessel until the oxygen has been all absorbed and the solution in the burette is of uniform strength with that in the store vessel. The liquor in the laboratory vessel is brought to the neutral point by allowing the indigo solution from the other burette to run into it. It is emptied through the syphon and rinsed with boiled water through the tapped funnel. The apparatus is now ready for standardising the hydrosulphite against the standard copper solution or against the standard indigo solution and for titrating the sample. These measured volumes are introduced through the tapped funnel, and this is rinsed with boiled water.

The mounting of the apparatus is troublesome, but when once it is set up any number of tests can be done with very little more trouble than an ordinary titration, and, as compensation, we have results which are thoroughly reliable. The indirubine is estimated as indigotine. The results obtained by this hydrosulphite acid method are about 0.3 to 0.4 per cent. of the indigotine higher than those obtained by the nitrobenzol method above described. This I attribute to the small loss of indirubine there pointed out.

MR. F. J. R. CARULLA IN THE CHAIR.

ON SOME PROPERTIES OF FERRIC PHOSPHATE.

BY R. M. CAVEN, B.Sc. (LOND.), A.I.C.,

Lecturer and Demonstrator in Chemistry, University College, Nottingham.

IN analysing the ash of the root of a ginger containing a fair amount of phosphoric acid combined with iron, aluminium, calcium, magnesium, &c., I was anxious, if possible, to ascertain the method of distribution of the PO_4 radicle among the metallic radicles present. With this object in view, I consulted one of the several phosphate tables which profess to indicate the presence of certain metals as phosphates. With the precise significance of the expression "presence of Fe, &c., as phosphate," I am not, in the present paper, concerned; suffice it to say that once the solution of a complicated mixture of phosphates is effected by means of an acid (e.g., dil. HCl) it is then impossible by any known analytical methods to discover how the phosphoric acid in solution was originally distributed throughout the solid substance.

If NH_4HO is added to an HCl solution of a mixture of phosphates, the PO_4 radicle will be precipitated in conjunction with metals which form phosphates insoluble in the supernatant liquid present, i.e., dilute NH_4HO solution together with soluble salts.

The distribution of PO_4 in this precipitate does not necessarily bear any relation to its distribution in the original solid substance; in fact the PO_4 radicle acts apparently as a free ion in the liquid, and in the presence of NH_4HO attaches itself to those metallic ions present which will form insoluble precipitates by union with the PO_4 radicle.

In what way the PO_4 will distribute itself between the various metals present capable of forming insoluble salts, and whether the proportions of the insoluble phosphates originally present in the solid state will, as a general rule, have any influence as regards the reprecipitation of these salts from solution, is a question upon which I cannot pronounce any definite opinion. To state the problem in a general way we may say that the active masses of all the ions present must be considered as affecting the result; and during precipitation these active masses are rapidly changing by the removal from participation in the changes going on of the matter precipitated.

Hence the solubility of the various phosphates which could theoretically be formed will have a great influence upon the proportions in which the insoluble phosphates will be present in the precipitate in any particular case. The affinity coefficients of the various ions will have little or no influence in this as in other cases of precipitation. Whether there is any predisposing tendency for reprecipitation of phosphoric acid in conjunction with the metallic ion with which it was originally combined in the solid state,

or whether the PO_4 radicals are free to rearrange themselves in an entirely new fashion, would seem, however, to be answered, in part at least, with regard to iron by the following experiment.

If FePO_4 is digested with cold, dilute HCl and the excess of FePO_4 removed, after a short time, by filtration, a solution is obtained which is almost colourless. If strong HCl is then added to this solution a bright yellow colour is produced, similar to the colour of a solution of FeCl_3 in water. If H_2SO_4 is substituted for HCl , and the experiment performed as before, little or no change of colour is produced on adding the strong acid. The most obvious interpretation of these facts is that it is possible to make a solution of FePO_4 in a dilute acid in which the double decomposition with the production of free H_3PO_4 does not take place to any extent, and that on addition of excess of acid, the latter acts by virtue of its mass so as to bring about the double decomposition.

The yellow colour with HCl in excess will then be due to the formation of FeCl_3 , and little change of colour is noticed with strong H_2SO_4 , because $\text{Fe}_2(\text{SO}_4)_3$ is nearly colourless. The yellow colour may be produced in the H_2SO_4 solution, even after the addition of strong acid by adding a large excess of strong HCl . We must then suppose that the pale solutions of ferric phosphate and sulphate which can be obtained, do not undergo dissociation with the liberation of ferric ions, or revert to the old view that the colour of the solution is simply that of the dissolved substance. This would certainly seem to offer a better explanation of the colours of the solutions of bright yellow ferric chloride, and pale ferric phosphate and sulphate, respectively.

This, however, does not touch the main question of the independence of the ions as regards precipitation purposes, because decompositions of salts and fresh combinations may take place to a large extent in the act of precipitation; as, indeed, we represent them as taking place, by means of the ordinary equations.

The ash which I examined contained a considerable quantity of iron as well as phosphoric acid, and on adding NH_4HO to the HCl solution I obtained a precipitate containing, among other things, ferric phosphate (FePO_4).

In considering the problem of the way in which the iron existed in the original substance and also in the precipitate by NH_4HO , I was led to investigate the properties of ferric phosphate rather carefully; and the results which I now lay before you are the outcome of observations of my own, supplementary to, and in extension of, the work of others on the subject.

The following is the information with regard to the properties of FePO_4 which I have been able to gather from various sources. FePO_4 is said to be only partially precipitated from acid solution by NH_4HO , and the reason attributed is that unless excess of iron is used, a phosphate will be formed which dissolves in ammonium hydrate. On the other hand, FePO_4 is soluble in excess of FeCl_3 , so that the complete precipitation of phosphoric acid in ammoniacal solution by iron is interfered with both by excess of NH_4HO and of FeCl_3 . *Rammelsberg* (Watts' Dict., 1877 Ed., art. *Phosphates*) found that on boiling FePO_4 with ammonia, a basic phosphate, containing an excess of iron, was formed, and he assumed from the fact that this basic phosphate did not appear to be constant in composition, that it consisted of a mixture of $\text{Fe}(\text{OH})_3$ and FePO_4 .

In order to test these conclusions and see what bearing they had upon the precipitation of FePO_4 by ammonia, I proceeded to prepare some FePO_4 in as great a state of purity as possible. In several attempts which were made to prepare FePO_4 , some curious results were obtained. In one case a certain quantity of a solution of FeCl_3 of known strength, from which free HCl was carefully excluded, was added gradually, and with constant stirring, to an equivalent quantity of $(\text{NH}_4)_3\text{PO}_4$ solution contained in a porcelain dish. A white precipitate of FePO_4 formed at first, and seemed to increase up to a certain point, after which the precipitate commenced to re-dissolve in the liquid, until just about at the point when the equivalent quantity of iron solution had been added, the precipitate disappeared altogether, leaving an almost colourless solution, containing

nothing but FePO_4 and NH_4Cl in approximately equivalent quantities. It was hoped that on evaporating this solution down, the FePO_4 would be recovered, but although at a certain stage small crystals made their appearance, no distinct precipitation occurred until near dryness, when the residue contained a considerable quantity of FeCl_3 , and was useless.

The idea of precipitating equivalent quantities of Fe and PO_4 was not however, abandoned, and the precaution of adding a solution of $(\text{NH}_4)_3\text{A}$ acidified with H_2A , in which FePO_4 is insoluble, was resorted to. The FePO_4 was produced as a white precipitate on mixing equivalent quantities of the iron and phosphate solutions, and this was washed with hot water until the washings were free from chlorine. A lot of PO_4 appeared in the wash water, and only a trace of iron. The precipitate was dried, and appeared dark coloured, as if contaminated with Fe_2O_3 . On ignition, the mass went dark red, and appeared like Fe_2O_3 , so that we may consider that the original precipitate was basic, or else underwent considerable decomposition during the process of washing.

The method which was found most satisfactory was as follows:—

FeCl_3 solution was added to a solution of H_3PO_4 —made by boiling glacial metaphosphoric acid with water until it ceased to give a precipitate with BaCl_2 solution—in such proportions that rather more than twice as much H_3PO_4 was present as was necessary to precipitate the iron. The precipitate thus obtained appeared, when suspended in water, perfectly white, and when strained on calico had a slightly bluish tint.

The first filtrate contained, as might be expected, much PO_4 and a trace of Fe . The precipitate was washed repeatedly with hot water in a large beaker of about 2 litres capacity, the supernatant liquid being removed in each case, when the precipitate had subsided, by means of a siphon. Careful experiments were made this time in order to verify the apparent decomposition of FePO_4 by water. The parts per 1,000,000 of chlorine and acidity, reckoned as HCl , in the three final washings, were as follows:—

Chlorine.	Acidity as HCl .
10	7
12	29
2	14

Thus the ratio of acidity to chlorine as chlorides increases rapidly as washing proceeds. Moreover, not a vestige of iron appeared in any of the final washings. These facts therefore establish beyond doubt the *hydrolysis* of FePO_4 by hot water, and explain the high percentage of iron found in former specimens of FePO_4 , which had been carefully washed and gently ignited until they ceased to lose weight. The percentages of iron found in two samples were respectively 43.02 and 43.52, whereas the theoretical percentage for $\text{FePO}_4 = 37.08$.

Having established the fact of the slow hydrolysis of FePO_4 by water, it is natural to expect that more powerful agents, viz., aqueous alkalis, would also effect the decomposition, and such is actually the case. Mention has already been made of the fact that *Rammelsberg* obtained a basic phosphate by boiling FePO_4 with NH_4HO . I have found that by continued boiling practically all the PO_4 may be extracted and $\text{Fe}(\text{OH})_3$ left behind, according to the reaction $\text{FePO}_4 + 3\text{NH}_4\text{HO} = \text{Fe}(\text{OH})_3 + (\text{NH}_4)_3\text{PO}_4$.

The results obtained were:—

Estimated percentage Fe in FePO_4	43.0
Percentage Fe calculated from $\text{Fe}(\text{OH})_3$ obtained....	43.6
Estimated percentage PO_4 in FePO_4	59.3
Percentage PO_4 obtained from solution after boiling....	58.3

The achievement of the above reaction depended upon the presence of a large excess of NH_4HO , and this reagent was renewed at intervals, during the process of boiling, which lasted many hours. The reaction is only completed by the agency of a large excess of NH_4HO , because in the

presence of a soluble phosphate the reverse change takes place, viz., $\text{Fe}(\text{OH})_3 + (\text{NH}_4)_3\text{PO}_4 = \text{FePO}_4 + 3\text{NH}_4\text{HO}$.

To prove this I boiled freshly precipitated $\text{Fe}(\text{OH})_3$ suspended in water with $(\text{NH}_4)_3\text{PO}_4$ in a porcelain dish. A strong smell of NH_3 gas was perceived and the colour of the precipitate rapidly changed from reddish-brown to yellow, and after an hour's boiling the suspended matter presented exactly the appearance of freshly precipitated FePO_4 , so that the reaction is reversible and we may write it thus:—

The direction which the reaction takes depends, as in other reversible reactions, upon the active masses of the constituents, and the formation of ferric phosphate from the hydrate is easier and speedier than the reverse process, because the latter is largely prevented by the removal of the volatile NH_4HO as soon as formed in the process of the reaction. On the other hand, the difficulty of bringing about the formation of ferric hydrate from phosphate is accounted for, also, by the volatility of the NH_4HO , which is required to be in excess, and by the presence in the solution of all the $(\text{NH}_4)_3\text{PO}_4$ formed during the decomposition.

Ferric phosphate dissolves in NH_4HO to a brown solution, which is decomposed with the deposition of $\text{Fe}(\text{OH})_3$ on further heating with NH_4HO , and $\text{Fe}(\text{OH})_3$ dissolves in $(\text{NH}_4)_3\text{PO}_4$, forming a solution which deposits FePO_4 with the evolution of NH_3 on further boiling. So that the formation of complex mediating solutions, seems to play a part both in the direct and the reverse reaction, though this phenomenon is relatively unimportant, since most of the solid matter never enters into solution.

DISCUSSION.

Mr. Wood said that Mr. Caven's discovery of the washing out of phosphoric acid by water from ferric phosphate would certainly be of great interest both to analytical and technical chemists. Although it seemed to be known that the analysis of this body was not capable of great accuracy, it was not known why this was so. It was to be hoped that all new editions of analytical tables and text books would give the general analyst the benefit of Mr. Caven's discovery.

The CHAIRMAN remarked that Percy had verified in his laboratory the statement of Pierre that water saturated with CO_2 dissolves nearly $\frac{1}{1000}$ of its weight of phosphate of protoxide of iron. Mr. T. Phillips, who conducted the investigation in Percy's laboratory, found that when saturated with CO_2 at the ordinary pressure of the atmosphere, water dissolves 0.54 part by weight of the phosphate in 1,000 parts of solution, which is little more than half of what had been previously looked upon as correct. He would like to know whether Mr. Caven had had any experience of this solvent.

Mr. LOXLEY MEGGITT said that one inference to be drawn from Mr. Caven's interesting paper was that in the estimation or precipitation of iron as phosphate the solution after the addition of ammonia should be boiled no more than was necessary, or else partial decomposition of the ferric phosphate might occur. He had always understood that in the precipitation of iron as phosphate from any phosphatic material, ammonia should only be added in slight excess. It appeared from Mr. Caven's paper, if too large an excess of ammonia were added the reverse reaction was apt to take place, in which the precipitated phosphate would be converted into ferric hydrate and ammonium phosphate. It was stated by Mr. A. Smetham in J.S.C.I., 1893, page 114, that unless an ammonium salt be used in washing a double precipitate of iron and aluminium phosphate, there was a tendency for the precipitate to split up into a basic phosphate, and a portion of the iron and alumina might wash through the filter. The most accurate method of precipitation of iron as phosphate was to add ammonia in slight excess to the cool hydrochloric acid solution of the substance, then add HCl drop by drop until the liquid was again quite clear, and then sufficient ammonium acetate to convert the HCl into ammonium chloride, stir well, let stand some time,

filter, and wash, first with cold water and finally with hot. (J.S.C.I., 1893, page 115.)

Mr. R. M. CAVEN said, in reply, that Fresenius had mentioned that the estimation of phosphoric acid as ferric phosphate was liable to be inaccurate, owing to the solution of the precipitate in the wash water. His own opinion was that ferric phosphate was insoluble in water, but that it suffered hydrolysis by continued washing, since while phosphoric acid continually made its appearance, he did not find in his experiments that iron appeared in the wash water. If FePO_4 were dissolved unchanged the residue would not be basic, and Fresenius noticed the alteration in composition of the precipitate by continued washing.

He was of opinion that this method of estimation of iron or phosphoric acid was necessarily inaccurate, because of the apparent impossibility of freeing the precipitate from dissolved salts, without at the same time decomposing it. He had had no experience of the action of carbonic acid on ferrous phosphate.

A METHOD OF SILVERING GLASS.

BY J. T. WOOD.

Mr. J. T. WOOD, the hon. local secretary, exhibited a simple process of silvering glass, which he had used many times for silvering the speculum of an astronomical telescope. The first process for silvering glass was that of Liebig, a description of which would be found in Roscoe and Schorlemmer's Chemistry, Vol. II., pt. I., p. 363. Other processes were the Rochelle salt, Brashear's, Petitjean's, and Martin's process (Monthly Not. R.A.S., Dec. 1875).

The present process was in the English Mechanic, Vol. LIX., p. 85. With care it gives very certain results and good films.

The subject of thin mirror films having recently come up before the Liverpool Section, he thought a practical illustration might interest the members.

Mr. Wood took a solution of silver nitrate, strength 1 grm. to 20 c.c., to which strong ammonia was added until the precipitate just re-dissolved. A solution of potash was then added, the weight of the KOH being exactly equal to the silver nitrate.

The precipitate formed was again dissolved in ammonia, the addition of ammonia being stopped before the whole of the precipitate was dissolved and the solution filtered. To the clear filtrate nitrate of silver solution was again added till the liquid had the colour of weak tea. The glass to be silvered was placed in a shallow dish, and so supported as to be raised half an inch from the bottom; distilled water was then poured into the dish until it reached the lower surface of the glass.

The glass was raised and the solution as above prepared mixed thoroughly with the distilled water. (The strength of the silvering solution was calculated so that 1.4 grm. silver nitrate = 100 c.c. water.)

A solution of dextrose of half the weight of silver nitrate was added, and the glass replaced. The dextrose slowly retaced the silver and a very perfect mirror was produced in 15 to 20 mins. It was explained that one of the chief elements of success is that the surface of the glass to be silvered should be chemically clean.

Mr. Wood exhibited a 10-in. speculum thus silvered.

SESSION 1895-96.

Tuesday, February 4th, 1896, at the Philosophical Institution, Edinburgh.—Mr. D. B. Dott. "Opium Assaying."

Meeting held in the Philosophical Society's Rooms, 207, Bath Street, Glasgow, on Tuesday, January 14th, 1896.

DR. JOHN CLARK IN THE CHAIR.

A METHOD OF OBTAINING THE SPECIFIC GRAVITY AND POROSITY OF COKE.

BY W. CARRICK ANDERSON, M.A., F.R.S.

THE determination of the true specific gravity of coke is a tedious operation, owing to the difficulty of removing the occluded gases from the pores.

The only method I have been able to find on record is that used by F. P. Dewey in determining the specific gravity and porosity of American cokes, which he describes in "Iron" of 22nd October 1883 (Vol. XXII., p. 376). That method is, shortly, as follows:—Suitable specimens (of from 20—40 grms.) are selected, brushed free from dust, dried, and weighed in air. They are then filled with water by being allowed to soak for 12—24 hours, afterwards placed under the receiver of an air-pump, from which the air is exhausted from three to five times, then boiled for three hours in water, and finally exhausted again at intervals till air-bubbles cease to come off. To make sure that saturation is complete, the exhaustion is repeated six to eight times. The saturated specimens are weighed first in water, and thereafter the water is allowed to run off as completely as possible, and they are then rapidly weighed in air. These three weighings furnish the data necessary for calculating the apparent specific gravity, the real specific gravity, and the porosity or percentage volume of pores.

If p = weight of dry coke in air,

q = weight of saturated coke in air,

r = weight of saturated coke in water,

S_1 = the apparent specific gravity,

S_2 = the real specific gravity (specific gravity of the particles),

C = the percentage volume of pores (porosity),
Then—

$$S_1 = \frac{p}{q - r}$$

$$S_2 = \frac{p}{p - r}$$

$$C = \frac{q - p}{q - r} \times 100$$

An objectionable feature in this process is the weighing of the coke with a necessarily variable amount of adhering water, which, moreover, evaporates continuously during the operation. There is the further drawback that it is not possible to get a result in this way in less than 24—36 hours, and it was principally to shorten the time required that I was led to adopt the following plan. The time occupied by my process is about $3\frac{1}{2}$ hours. An average sample of coke is prepared, and of this 45—50 grains ($3-3\frac{1}{2}$ grms.), previously ground in a Wedgwood mortar to a condition resembling fine sand, and dried, is weighed out in a dry tared specific-gravity bottle. The sample is then covered with about an inch of water, and the bottle is placed in a beaker of water kept at a temperature of 90° — 100° C. The neck of the flask is attached by a tube to a Bunsen water-pump with a good supply of water, and the air exhausted. The exhaustion is kept up for $2\frac{1}{2}$ hours, a gentle ebullition being meanwhile maintained. The tube is then detached, the bottle filled up with water, subsequently brought to the correct temperature, dried, and weighed.

Weight of dry sample.

Sp. gr. = $\frac{\text{Weight of (bottle + sample + water-content of bottle) - Final weight of (bottle, sample, and water required to fill)}}{\text{Weight of dry sample}}$

To test the accuracy of the method, six samples of coke were taken, of the following composition before drying:—

	A.	B.	C.	D.	E.	F.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Moisture	0.20	0.21	0.19	0.63	0.17	0.53
Ash	8.06	6.07	5.10	8.69	7.25	8.43
Volatile matter	0.50	0.35	0.30	0.47	0.71	0.57
Fixed carbon ..	91.24	93.37	94.41	90.21	91.87	90.47
Sulphur	100.00	100.00	100.00	100.00	100.00	100.00
	0.79	0.90	0.92	1.07	1.79	1.23

In the following table the first set of figures gives the specific gravities found for these samples by the method described above; the second set, the results got by exhausting similarly powdered samples with an air-pump, as described by Dewey. The third set contains results got for some of the cokes by Dewey's method, using the samples in small fragments:—

	A.	B.	C.	D.	E.	F.
Real specific gravity got by new method	1.838 1.842 1.837	1.818 1.820 1.818	1.841	1.846	1.889	1.879 1.878 ..
Real specific gravity got by air-pump method (with powdered samples)	1.847 ..	1.832 ..	1.840 ..	1.850 ..	1.891 1.891	1.879 ..
Real specific gravity got by Dewey's method (with fragments)	1.623 1.626	1.700 1.660	1.703 1.699	1.730 1.728

¶ The last set of figures was got after the fragments of coke had been soaked for 24 hours, then placed in water under the receiver of air-pump for 18 hours, and afterwards boiled and exhausted alternately, and allowed to soak until they had been altogether seven days under water. Finally, they were exhausted under water with a Bunsen pump for two hours. The fact that the results thus obtained are uniformly much lower than those got by powdering the samples, seems to point to the existence of water-tight

vesicles in the coke, which prevent its complete saturation. The researches of Dr. W. Thörner (Stahl und Eisen, Vol. VI., pp. 71—83) have been held to show (Mills and Rowan, "Fuel") that, "whereas charcoal consists of a large number of more or less regularly arranged cells, which are joined to one another longitudinally, coke contains generally separate unconnected cells, or groups of cells, the walls of which are composed of a dense and vitreous mass which does not admit of the passage of gas through it."

The results of a series of experiments I have made on various coals in fragments seem to confirm the latter statement, and to lead to the conclusion that it is impossible in this way to remove all the gases from the pores.

The figures got above are sometimes called the "apparent specific gravities" of the samples, but it seems more correct to call such results the "real specific gravities," seeing that they give the true specific gravity of the coke particles; and this title I have given them throughout.

To ascertain the percentage volume of pores in a coke sample, or the volume of the pores in 100 parts by weight, it is necessary first of all to know the apparent specific gravity, or the relation between the weight of the coke sample and the weight of a volume of water at 4° C. equal to the volume of the particles and the pores of the coke taken together. This can be rapidly and accurately obtained by means of a simple "volumenometer" which I have designed in conjunction with Mr. J. Stanley Muir, B.Sc.,

primarily for this purpose, although it is equally available for ascertaining the specific gravity of all insoluble bodies, ores, alloys, &c., which can be obtained in fragments of suitable size, whether the bodies be lighter or heavier than water. The instrument consists of two parts, one of which, A, is a receiver capable of holding 25–100 c.c. of water. This is closed at the top by an accurately fitting, hollow glass stopper, which is prolonged upwards into a narrow tube closed by a stop-cock. The receiver is connected at the bottom by means of a piece of nitrometer tubing with the measurer B, which is an ordinary glass burette capable of being read to $\frac{1}{10}$ c.c., and the whole instrument is clamped to a suitable stand.

To obtain the specific gravity of a solid, the measurer is moved up and down so as to fill the receiver with water exactly to the level of the stop-cock, which is then closed, and the reading on the measurer taken. The stop-cock is next opened, and part of the water in the receiver caused to flow into the measurer, and the stopper is then removed to admit the weighed sample. The dry sample, brushed free from dust, should be from 5 to 30 grms. in weight, and in the case of coke should be in fairly large pieces. When the sample has been gently placed in the receiver, the stopper is replaced and the water caused to return to the level of the stop-cock, which is then closed. The instrument is next shaken to detach adhering air-bubbles, which are allowed to escape, and a new reading is taken. Ten minutes,

or at least equal intervals of time, should be allowed to elapse before taking each reading, to admit of the liquid running down. The difference of the two readings gives the volume of the sample in c.c.'s, which at the ordinary temperature may be assumed with sufficient accuracy to represent an equal number of grms. of water, and therefore,

$$\text{Apparent specific gravity} = \frac{\text{Wt. of sample in grms.}}{\text{Volume in c.c.'s.}}$$

In the case of coke, using 12–20-grm. samples, results can be got differing only in the third decimal place, thus:—

Apparent Specific Gravity by New Volumenometer.

Sample.	A.	B.	Difference.
I.	1.012	1.038	0.004
II.	0.923	0.919	0.004
III.	1.212	1.206	0.003
IV.	1.088	1.091	0.003
V.	1.017	1.027	0.010
VI.	1.080	1.071	0.009
VII.	1.025	1.022	0.003

Combining the figures thus obtained with those representing the real specific gravity, we get the porosity or percentage volume of pores in a sample, and also the volume of pores in c.c.'s per 100 grms. of coke.

$$\text{Porosity} = \frac{(\text{Real sp. gr.} - \text{Apparent sp. gr.}) \times 100}{\text{Real sp. gr.}}$$

$$\left. \begin{array}{l} \text{Volume of pores in c.c.'s} \\ \text{per 100 grms. coke} \end{array} \right\} = \frac{\text{Porosity}}{\text{Apparent sp. gr.}}$$

The following table gives examples of such results:—

No. of Sample.	Real Sp. Gr.	Apparent Sp. Gr.	Porosity.	Volume of Pores in c.c.'s per 100 Grms.
1	1.854	1.040	43.91	42.22
2	1.837	0.921	49.86	51.13
3	1.936	1.210	37.50	30.90
4	1.837	1.089	40.72	37.39
5	1.873	1.022	45.44	44.1
6	1.850	1.075	41.89	38.97
7	1.913	1.023	46.52	45.47

That the relationship between the volume of the pores and the weights of combustible material in a coke has an important bearing upon its efficiency in the furnace, is generally admitted, but, so far as I know, it has not been usual to make systematic determinations of the figure for coals produced by the various types of oven working on different coals. This is perhaps largely due to the troublesome and tedious nature of the operations involved in exhausting with air-pumps to remove the gases from the pores of the coke fragments.

The publication of figures showing the porosity and the ash-content of average samples of the coke made in various districts and works, could not fail to be both interesting and instructive, provided these figures were obtained by a uniform method of experimenting. The method suggested above affords a means of arriving at the porosity quickly, with little trouble, and by the use of simple apparatus; and, in the belief that on this account it may be of practical utility, I have ventured to lay it before you.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

Refrigerating Machinery, New Improvements in.
 Wochenschr. f. Brauerei, 1895, 12, 602—604.

REFRIGERATING machinery can be divided into three classes:—

- (1) Absorption machines, such as ammonia machines.
- (2) Vacuum machines, such as those in which water vapour is absorbed by sulphuric acid *in vacuo*.
- (3) Compression machines, in which ammonia, carbon-dioxide, or other substances are liquefied by compression, the liquid, when allowed to evaporate, producing cold.

(1.) The most recent absorption machines are improvements of the old Carré machine. Only the weaker ammonia solution is boiled; the ammonia is expelled from the strong solution by leading the gas from the boiler through it. Another improvement is to divide both the boiler and the absorber into chambers, in the innermost of which is the worm through which respectively passes steam or cooling water; by this arrangement the stronger solutions are separated from the weaker ones. However, these machines will not bear comparison with compression machines.

(2.) The vacuum machines are not capable of much improvement. In the newest, a separate apparatus is provided for concentrating the sulphuric acid, but this is at best unsatisfactory. These machines are not used to any extent.

(3.) In contrast to the two above-described machines, the compression machines have been greatly improved of late. There has been no alteration in the general style of construction and working. The valves are now made with wide seatings and the stuffing boxes with metal packings. For high pressures, leather backed with india-rubber has been used with success in the pistons and the stop-valves. Glycerin is used as a lubricant for leather and Baku oil for metal on metal.

The use of superheated steam is found to be useful, as thereby the loss of power by condensation is avoided. On the other hand, this leads to an increased decomposition of the oil which it is necessary to use in the ammonia cylinder.

* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to Sir Henry Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

It has also been found advisable to allow only a fixed quantity of the liquefied substance to pass from the compressor to the evaporator at one time.

Every increase in the difference of temperature between the cooling water and the refrigerating solution diminishes the efficiency of the apparatus. This is a most important point, and unless a proper relation exists between the constants of the refrigerating material and the temperature of the water, the efficiency of the machine is much diminished—A. L. S.

PATENTS.

Improvements in Apparatus for Raising or Pumping Corrosive or other Liquids. T. T. Best, Ph.D., S. A. Hollingsworth, and J. Brock, Liverpool. Eng. Pat. 17,593, Sept. 15, 1894.

THE object of this invention is to dispense with the labour and attention required in raising corrosive liquids, by means of large strong eggs or montejus and compressed air, and by rendering the operation automatic and practically continuous.

The liquor to be raised passes through the inlet valve B in the vessel A, standing in or connected with the cistern C.

To A is connected a pipe E, conveying compressed air, which passes through the four-way hollow-plug tap L. To the plug of this tap is attached a toothed wheel I, rotated by the worm wheel M, which latter is kept revolving by any suitable means. In the position shown in the figure, compressed air enters through the pipe E into A and forces the liquor along D to its destination; whilst A¹ exhausts itself of the air from a previous compression through E¹ E² and at the same time refills itself with liquor through B¹.

When the valve L revolves to the opposite angle, the compressed air will enter through E E¹ into A¹, and A will then exhaust its air through E E² and fill itself with liquor ready for another compression. The apparatus must of course be made of materials able to withstand the action of the liquor being raised. Seven different patterns of valve arrangements are shown for the above purpose.

A Homogeneous Mixing Product of Mealy or Powdered Substances of Heterogeneous Composition, Mode of Preparing, and in Apparatus therefor. O. Fåhnehjelm, Stockholm. Eng. Pat. 20,781, Oct. 30, 1894.

THE "meal" or powder is caused to fall down on the upper part of inclined planes or floors, so arranged one above the other, that the lines of inclination shall represent those observable in the contour of the upper surface of the heap formed, when the material referred to has been allowed

to fall down freely on to a horizontal plane. These conditions are practically those observed in the spread and formation of the lower sand heap, when a sand-glass is used.

Such a distribution of the particles in thin layers covering each other is so effected that the complete homogeneity desired, is secured. Further uniformity is obtained by the arrangements for emptying the floors and for filling the meal collars.—V. C.

Boiler and other Furnaces, Improvements in or relating to. J. Sutton, Freshfield, Lancashire. Eng. Pat. 21,052, Nov. 2, 1894.

STEAM boiler- or other furnaces or flues are formed inside the flue in proximity to the bridge, with an air reservoir having an orifice for discharging air under the grate, and another orifice for discharging air through the bridge, in combination with air-supply pipes or channels leading through the flues from the front of the furnace to the air reservoir.

The foregoing arrangement in combination with means for inducing a forced draught is further claimed, viz., by injector nozzles through which steam is discharged.—R. B. P.

Furnaces for Treating Chemicals, Ores, or the like, Improvements in or connected with. W. Thomson and P. J. Worsley, Bristol. Eng. Pat. 21,946, Nov. 13, 1894.

IN furnaces for the manufacture of ultramarine, the heating of sodium bicarbonate, the chlorination of silver ores, the roasting of blende, or the distillation of shale, and for other purposes in which it is desirable to heat the charge without contact with fuel gases, the inventors apply the system of a furnace heated from flues beneath, and with a revolving roof carrying a stirrer frame, the roof being either single or double. The stirrer frame carries rotating stirrers, and another frame may be added carrying ploughs

to turn over and discharge the contents of the furnace; or the frame with ploughs only, may be used. In order to heat the space under the arch, or between the two arches (in the case of a "closed furnace"), a fireplace is supported on the roof, the fuel gases from which pass through suitable apertures in the arch or the upper arch into the space beneath, and are withdrawn by flues leading to a chimney. Provision is made for continuous feed and discharge, as well as for withdrawing gaseous products.—E. S.

Filter Presses, Improvements in. J. Hill Fenton, Stoke-on-Trent. Eng. Pat. 22,645, Nov. 23, 1894.

AN apparatus for making potters' clay, compressing yeast, paraffin, sewage, and the like. It comprises a number of porous tiles held in frames and perforated by central longitudinal channels, so that the fluid to be filtered can pass freely from the outer filtering surface to the inner channels, and from thence can be drawn off by suitable outlet pipes. The frames are protected from contact with the material to be filtered by wood strips, and the cleansing of the tiles is effected by forcing or raising water through the outlet pipes.—E. G. C.

Distilling Apparatus, Improvements in. N. Yagu, St. Petersburg, and S. Bessonoff, St. Petersburg. Eng. Pat. 827, Jan. 12, 1895.

THE distilling apparatus is for producing distilled water or other liquid by means of a series of multiple liquid evaporators at the expense of the heat of a single quantity of steam, preferably high-pressure steam taken from a boiler. Successive evaporations at gradually decreasing temperatures are performed in a series of an indefinite number of closed metallic vessels A, provided with heating batteries B, of any form or shape of heating surface, so that the heating battery of each following vessel forms the

condenser for the preceding vessel. The steam from the boiler is led by a tube to the heating battery of the first vessel, where it condenses, and is generally returned to the boiler by a tube. The steam formed in the first vessel by the action of the heating battery therein, passes by the tube *d* into the battery of the second vessel, in which it condenses and causes the water in the second vessel to boil; the steam so generated passes into the battery of the third vessel, and so on, until the last vessel is reached, and steam from this is led to the condenser *B¹*. The water of condensation from each battery, except in most cases the first, is led by a tube *K* past a throttle valve *x*, which condenses any steam therein, and thence to the tube *d*, and on to the next battery. The condenser is placed in a tank *M*, continuously filled with cold water, and the heated water obtained therein is used to feed the vessels *A* by means of the tubes *a* and cocks *y*. A partial vacuum may be obtained in the condenser by means of a steam pump, or by providing a descending outlet thereto. The vessels *A* may be arranged in an ascending and descending order, such an

arrangement being also illustrated. A device is shown and described for drying the steam passing from one vessel to the next battery. Another device consists of heat transferers for preventing a deposit of salts on the tubes of the vaporising batteries when the feed water is saline, whilst a third consists of mechanism having a valve, operated by a rubber bag filled with water, for automatically maintaining a constant level in the distilling vessels.—R. S.

Smoke-consuming Furnaces, Improvements in or relating to. J. V. Gane, Paris. Eng. Pat. 11,185, June 6, 1895.

THE fire-box roof is built of bricks in which there are two separate sets of perforations. Through the first of these, the products of combustion pass from the furnace, and in doing so heat the brickwork. Air is introduced through the second set, and in passing along them is heated. These perforations terminate on the under side of the arch, and the heated air issuing from them meets the hot gases just as they are about to pass through the perforated arch, thus ensuring complete combustion.—R. B. P.

Raising or Forcing Liquid and Semi-Liquid Substances, Improvements in Apparatus for. A. Goodwin, Southwark, and T. Clay, Gravesend. Eng. Pat. 13,317, July 10, 1895.

Liquid and semi-liquid substances are raised from pits, wells, bore-holes, reservoirs, and other places, by means of compressed air, alternately admitted to and exhausted from each of two annular displacement chambers, adapted to be alternately placed in communication with a discharge pipe, and with the body of the liquid to be raised or forced. Two air tubes reaching down to the displacement chambers are provided, and are connected at their upper ends to an air-distributing valve, whereby alternately each tube is open to the atmosphere and is placed in communication with the compressed-air reservoir. To facilitate the outflow of air from the chamber to the atmosphere, compressed air is caused to blow over the top of the air-tubes: (a) By providing air ejection passages in the valve casing, the outer ends terminating in or above the ports of the said pipes, and the inner ends within the casing between the pistons; (b) By perforating the piston valves; or (c) By allowing a stream of compressed air to blow around the outer periphery of the piston.—R. S.

Burners for Incandescent Lighting, Improvements in and applicable to. E. H. C. Oehlmann, Berlin. Eng. Pat. 13,467, July 12, 1895.

This invention is for the purpose of effecting improvements in burners for incandescent light, in such wise that the mixture of air and gas can be heated in the mixing chamber before ignition. In the case of lamps in which the gas or vapour is formed in the lamp itself from volatile liquid materials, as spirit, benzene, &c., the aim is also to provide means whereby this gas or vapour may be conducted with facility to the mixing chamber.—W. S.

Discharging or Transferring Liquids, Improvements in Pumps or Apparatus for. P. Brandell, Council Bluffs, Iowa, U.S.A. Eng. Pat. 17,080, Sept. 12, 1895.

The apparatus consists of a hollow tapered plug for screwing into the cask or tank to be emptied, from the upper part of which plug depends a telescopic tube, whilst a side inlet or nipple is provided for coupling up to an air compressor or force pump, whereby the liquid is forced up the telescopic tubing into the receiver.—E. G. C.

Filtering Apparatus for Purifying and Sterilising Liquids, Fluids, Gases, and Vapours, Improvements in. C. Tissier, Paris, and H. J. Ernaux, Paris. Eng. Pat. 18,857, Oct. 8, 1895.

The apparatus contains one or more tubular bodies (formed of tubes of wire gauze or other perforated or permeable material strengthened internally by a wire coil and a star or cross-shaped stay) which are so arranged within a closed vessel that the liquid, fluid, gas, or vapour to be filtered is made to pass transversely through the tubular bodies in the direction from the outside to the inside, a coating of filtering material, as paper pulp, being in the first instance formed on the outer surface of the tubular bodies by mixing such material in a finely divided state with a portion of the liquid, which then deposits the material upon the outside of the tubes as it passes through them. Two forms of apparatus are shown, having suitable external tubes, connections, and valves for depositing the filtering layers, for passing the liquid, &c. to be purified, for discharging the purified liquid, &c., and afterwards for detaching and carrying away the pulp and its accumulated impurities from the outsides of the tubes.—R. S.

II.—FUEL, GAS, AND LIGHT.

Coal-Gas Flames, On the Alleged Escape of Carbonic Oxide and Unconsumed Carbon from. L. T. Wright. J. of Gas Lighting, 66, 1895, 1023—1024.

The charge that carbonic oxide is contained in the normal combustion products of gas flames, and, further, that this gas is able to pass through the iron of heating stoves and their flues, is disputed.

Carbonic oxide only passes through cast and wrought iron when they are heated to redness—a condition non-existent in the case of gas stoves. Moreover, experience shows that gas may be safely used in dwelling-rooms without any risk of such a result.

M. Gréhan (Comptes rend. 119, 146) caused some excitement by alleging that the products of combustion from the Auer-Welsbach burner contained carbonic oxide; but since then Renk, Boshard, and, independently, Bunte, have disproved this. Finally, M. Gréhan admitted that the use of the Welsbach burner is unattended with any danger of carbonic oxide poisoning.

V. B. Lewes (Jour. Chem. Soc. 61, 323) states that from the tip of a gas flame there escaped unburnt 0.39 per cent. of saturated hydrocarbons and 1.18 per cent. of carbonic oxide, but the difficulty of collecting gases from any particular part of a flame is so great that it is probable the gases were really drawn from an integral part of the flame before combustion was complete. Landolt ("Ueber die chemischen Vorgänge in der Flamme des Leuchtgases") supports this view.

Thomson (Brit. Ass. Rep. 1890, 786) showed that combustion in various gas burners was not so complete as desired; but his results practically went no further.

Experiments carried out in the Laneet laboratory (Laneet, 1895, 51) on the products of combustion from Welsbach, Argand, and Bray burners gave distinctly negative results as regards carbonic oxide and acetylene in the first two, and but a doubtful indication in the latter.

The author has also on two occasions conspicuously failed to find any traces of unconsumed gas escaping from the normal flames of ordinary gas burners, both lighting and non-luminous. Although he prefers to arrange for the discharge of the products of combustion into the outer air direct, it is only on the ground of general considerations of comfort.

Given normal conditions, a free air supply, and no striking back of the flame, there seems to be no difficulty in the case of the worst burner, in effecting combustion of the gas, and the author does not believe any case of imperfect combustion in the directions named, has ever been substantiated.—R. S.

Coal-Gas, Investigations on. H. Bunte. Chem. Zeit. Rep. 1895, 19, 255.

Products of Combustion.—The amounts of carbon monoxide and other products of incomplete combustion were so small in the case of Argand, Auer, and Bunsen burners that the combustion must be regarded as practically complete. Thus, lighting by gas should not be injurious to health. (See preceding abstract.)

Comparison of Incandescent Burners.—The Auer burner surpasses in durability, quantity, and quality of light most of the 13 of its competitors with which it was compared.

Carburisation.—The increase in luminosity, due to benzene and toluene in water-gas, carbon monoxide, and hydrogen flames, was only equalled by that produced by three or four times the quantity of pentane and hexane. The two hydrocarbons of each class produced almost the same effect. In the decomposition of the paraffins by heat (600°–1,000° C.), hardly 2 per cent. of acetylene and aromatic hydrocarbons is formed; the chief reaction results in the formation of methane and homologues of ethylene.

—A. C. W.

Petroleum, Influence of the so-called Resinous Constituents on the Illuminating Power of. The Acid Test. K. W. Charitschkow. Trudy. bak. otd. imp. russk. techn. obschtsch. 1895, 10, Pt. 1, 39.

With the idea of determining whether the "acid test" with sulphuric acid of sp. gr. 1.53 can afford any indication of the illuminating value of petroleum, the author examined oils refined in the ordinary way, together with some that had only undergone the alkali treatment, and found that the latter gave a more constant light, though the resinous constituents had not been removed. He asserts that although it is generally considered that the effect of the sulphuric acid treatment is to render the oil less subject to oxidation and alteration, it has not yet been proved how far such

changes lower the illuminating power, and he therefore considers testing oil for thorough acid purification superfluous, so long as the advantages of this purification remain undemonstrated.—C. S.

Kerosene from Ohio Petroleum. R. Kissling. Chem. Zeit. 19, 1549—1550.

REFERRING to statements advanced at the 1893 meeting of the Bavarian Society of Applied Chemistry (Chem. Zeit. 19, 1452), Kissling points out that the amount of paraffin in burning oils is very slight, and can, in any case, only affect the utilisation of the oil—not its illuminating power. In connection with the assertion that Ohio oil, containing a large proportion of sulphur, is now in the market, necessitating the examination of such oil for the detection of sulphur, he remarks that those who ought to know, deny that refined Ohio oil is dealt in in Germany, but that even if it be, the desulphurising processes this oil undergoes in refining render it undistinguishable from the Pennsylvania oil, containing but little sulphur.—C. S.

Coal-Dust Fuel. C. Schneider. Mitt. aus der Praxis des Dampfkessel- und Dampfmaschinen-Betr. 1895, 336 et seq.; Proc. Inst. Civil Eng. 1895, 123, 56.

AFTER describing in detail the Wegener, Schwartzkopf, Friedberg, Kuhl, and De Camp systems for burning coal-dust, the author gave some details of trials of the Wegener system.

The working pressure was seven atmospheres.

The coal-dust, thoroughly mixed with air, is introduced into the end of each of the flues and there burnt; the hot gases then traverse the internal flues, the outer surface of the lower shell from back to front, the external heating surface of the upper shell from back to front, and lastly, the 72 tubes of the upper portion. Five different trials were made on this boiler.

For the trials on the double boiler three kinds of coal-dust—Oberschleswig, English, and Bohemian—with calorific values of 6,626, 6,516, and 5,264 heat-units respectively, were used. The analyses of the different coal-dusts are given. In the double boiler, the quantities of heat utilised were respectively 78, 79, and 78 per cent. of the total heat-values of the fuel; the steam production in four of the trials being considerably above the average with ordinary coal firing.

The excess of air used in the first five trials was 0.84 per cent.

In the first five trials it was evident that the ashes contained a considerable proportion of unburnt coal-dust; in the sixth trial, therefore, the ashes were analysed, from which it appeared that the heat lost, due to imperfect combustion, was 4.7 per cent.

The results of these trials, as compared with those obtained from the usual methods of burning solid fuel are said to be very satisfactory.

The author considers the advantages are—most perfect utilisation of the fuel, complete smokelessness, small amount of manual labour required, favourable results from any kind of fuel that can be applied in the form of dust, adaptability of the system to any kind of requirements, preservation of the boiler, and rapid removal of the fire in case of danger. The disadvantages are—the grinding of coal into a uniform dust before it can be applied, the necessity of mechanical power, the deposit of ashes in the flues and tubes.

PATENTS.

Carbon for Electrical and other Purposes, Improvements in the Manufacture of. C. P. Shrewsbury, F. L. Marshall, and J. Cooper, London, and J. L. Dobell, Modbury, Devon. Eng. Pat. 15,782, Aug. 18, 1894.

THE claims are for mixing anthracite coal (10 parts), bituminous coal (4 parts), and tar, or pitch and tar, in such proportions as to constitute a material which contracts when exposed to heat. The mixture, after being submitted to pressure, drying, and baking, is exposed to a high temperature. "It is of paramount importance that the temperature of the ovens should be raised and lowered very

gradually, as in operation of baking, the contraction of the material is so great that any sudden change of temperature would cause the article under treatment to crack or break."

—J. C. R.

Gas, Improvements in the Production of, by Electricity. J. H. Dunn, London. Eng. Pat. 19,433, Oct. 12, 1894.

THE material to be converted into gas—coal, petroleum, or other carbonaceous matter—is placed in a retort provided with one or several pairs of carbon electrodes. An "arc" is established between these, and the carbonaceous matter converted into gas by the heat given off by the arc.

—R. B. P.

Acetylene, Improvements in Gas Generators suitable for Producing. E. Gearing, Harrogate. Eng. Pat. 25,203, Dec. 28, 1894.

THIS apparatus is for producing acetylene from water and a metallic carbide—calcium carbide, for instance.

It consists of a vessel containing the carbide, into which the water is admitted through a valve, the amount the latter can pass being controlled by the pressure of gas in the generator. The production of the gas is thus automatically adjusted to the rate at which it is consumed.

—R. B. P.

Coal-Slime, Improvements in the Treatment of, and Apparatus therefor. G. Baehner, Bohemia. Eng. Pat. 14,883, Aug. 6, 1895.

COAL-slime is subjected to a preliminary separation in one or more settling tanks, and to a final separation of the coal and slime by means of an ascending water current, allowing fine uniform coal to fall down, while the slime is carried off with the ascending stream of water and overflows along with it.—R. S.

Incandescent Mantles for Lamps, Improvements in. S. H. Crocker, London. Eng. Pat. 15,246, Aug. 13, 1895.

A thin sheet of a suitable material—paper, for instance—is coated with the incandescing material, preferably a salt of erbium. The sheet is then perforated to give it a grid-like structure, and corrugated to increase the radiating surface. The edges are then cemented together to form a mantle of suitable shape, which is baked or carbonised to destroy the supporting sheet.

According to a second method, the supporting paper is first sized or gummed, then coated with collodion, and finally with the incandescing material.

By immersion in water, the paper can be floated off the coated collodion film. The latter is then perforated, corrugated, and carbonised, as in the first case. With the second method the amount of material to be destroyed by burning in the oven is much less.—R. B. P.

Glass Chimneys, An Improvement in or applicable to. G. F. Trautler, Hatton Garden. Eng. Pat. 17,842, Sept. 24, 1895.

THE chimneys (for burners and lamps) are divided longitudinally, the parts being held together by bands.—R. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Paranthracene. W. R. Orndorff and F. K. Cameron. Amer. Chem. J. 17, 1895, 658—681.

AFTER reviewing the researches on the preparation and constitution of paranthracene, recently made by Elbs and Liebig (this Journal, 1892, 340, and 1893, 512), the authors give an account of their own investigations on this subject, which were undertaken with the view to adduce further proof as to the correctness of the assertion that anthracene and paranthracene have the same percentage composition. All previous investigators seem to have been satisfied on this point, on the grounds that sunlight converted anthracene into paranthracene, and that on heating

the latter to its melting point (224°), it gave a product which, after solidification, fused at 213° , the temperature at which anthracene melts.

Paranthracene was obtained in a pure state by exposing purified anthracene suspended in benzene and xylene in thin white glass bottles to the direct action of sunlight for some weeks during the summer of 1894. When paranthracene ceased to separate out, the mass was filtered, washed with benzene, and dried. It was then boiled in a flask connected with a reflux condenser, first with alcohol, then with acetic ether, and finally with benzene. The residue—a pure white crystalline mass—was dried and recrystallised from benzene. The pure product formed a beautifully white crystalline substance, melting at 242° – 244° to a light yellow liquid. This, on cooling, solidified to a white mass with a green colour by reflected light, and melting exactly at 213° . It was found that both anthracene and this substance (paranthracene), have the same percentage composition. The specific gravity of the former at 27° , compared with water at 1° , is 1.250; that of paranthracene, 1.265. The latter differs from anthracene also in its crystalline form and optical behaviour. To determine the molecular weight, the method of boiling points was used, and the number found for this was 357. The formula derived for paranthracene was $C_{28}H_{20}$, a result in complete accord with that obtained by Elbs. The authors consider *dianthracene* a preferable name. As regards the constitution, they give a formula which is very similar to the one suggested by Liebig. They, however, show that it is erroneous to assume that paranthracene contains a ring of four carbon atoms.—D. B.

The Petroleum Lands of Germany. O. Lang.
Chem. Ind. 18, 318–313.

THROUGHOUT the north-west of Germany occurrences of petroleum and allied substances are frequent, especially in the valley of the Aller, but oil has been obtained in workable quantity only at Wietze and Oelheim. Plentiful supplies of pitch also occur in the former locality. At Oelheim the surface rock consists of diluvial clays and boulder sands from 15 to 40 metres in thickness. The chief source of oil in the underlying strata is a zone of sandstone widening out from south to north. Another productive belt near by rests on middle Jurassic strata. A great deal of gas is frequently encountered, and the oil is struck at moderate depths (up to 80 metres), but is accompanied by such large quantities of brine (10 per cent. of oil to 90 per cent. of water is a high proportion) that the cost of production is great, and for 12 months (1883–1884) the industry was discontinued on account of the prohibitive restrictions imposed for the treatment of the brine, which was causing much damage to the agriculture of the district. The future of the Oelheim oil-field will depend on the advance of knowledge concerning the origin and storage of petroleum in the earth.

The Alsatian oil-field, the most important workings of which are at Pechelbronn, extends, according to Jasper and Werveke, for a distance of 40 by 15 kilometres in the plain of Lower Alsace, and the petroliferous strata lie at moderate depths, the five oil-sands penetrated at Pechelbronn occurring at 80–90, 120–150, 180–200, 230, and 335 metres. The only two wells extending to a greater depth than the last-named figure failed to strike any other source. An unusually productive well (No. 146) yielded 200 barrels of oil daily from 1882 to 1886 without pumping, and the quantity amounted to 10,000 kilos. per diem when a pumping shaft was sunk in 1888.

The productive borings in the Rhine plain vary from 13.6 to 222.8 metres deep, the depth decreasing as a rule the further south they are situated. To the westward again the average depth of 212 trial borings was 25 metres, but none of these yielded workable quantities of oil.

Alsatian oil in the crude state is, like that of Hanover, mostly dense and dark-coloured, and, north of the Zorn, is frequently associated with asphaltic substances. The most remarkable peculiarities noticeable in this district are the high percentage of bromine in the water accompanying the oil, and the unusually rapid, though irregular, increase of temperature with the depth (60° – 6° C. at 620 metres).

Petroleum Difficult of Separation from Water and Tar, New Distillation Process for. R. A. Ostrejko. Trudy. bak. otd. imp. russk. techn. obschtsch. 1895, 9, Pt. 6, 1.

This method is designed for the purpose of preventing frothing up when petroleum containing water is distilled, and consists in blowing superheated steam into the still through a large rose situated a little above the surface of the oil. The finely-divided jets of steam impinge on the boiling oil, break up the foam, and carry away the vapours to the condenser.

In the case of tar, low-pressure steam is used, but the temperature is gradually raised during the progress of distillation until, by the time nothing but coke remains in the still, the steam is at 228° or thereabouts.—C. S.

Petroleum. Influence of Sunlight and Air on Petroleum Products. Capacity of Petroleum for Absorbing Atmospheric Constituents. R. A. Ostrejko. Trudy. bak. otd. imp. russk. techn. obschtsch. 1895, 10, Pt. 2, 21.

On exposure to sunlight and air, ordinary Baku petroleum of medium quality deposits a yellow sediment and becomes strongly acid, giving off at the same time a penetrating smell. Part of the deposit is soluble in distilled water, a dark, tarry substance being obtained on evaporation, and the remainder is dissolved by ethyl alcohol and concentrated sulphuric acid. Several samples of oil exposed in clear glass bottles to air and sunlight became opalescent in 9 hours, and subsequently turbid, with formation of sediment; whereas when kept under the same conditions in green bottles, the oils became appreciably lighter in colour. Further tests revealed the fact that in vessels of clear and blue glass, with admission of air, the oil darkened considerably on exposure to light; whilst in orange-yellow and green bottles the colour became lighter in 48 hours; and in the case of clear glass, with exclusion of air, scarcely any change occurred. The percentage of acidity increased some fivefold in three days in the blue and clear glass vessels, but remained practically unaltered in the others.

Several distillates refined in different ways all showed that the amount of acidity resulting on exposure increases concurrently with the deepening of the colour.

The effect of light in facilitating the absorption of air by the oil is very marked, a sample in a tube, into which a single bubble of air was admitted, absorbing it completely; whereas in a second sample, similarly treated, but kept in the dark, no absorption occurred, the air bubble, on the contrary, appearing to have increased in size.

For the purpose of determining whether the degree of refining influences the absorptive capacity of the oil towards air, a number of vessels were filled with ordinary oil, and others with oil that had been exposed for some time to light and undergone a subsequent refining with excess of acid and alkali. To the vessels were affixed eudiometer tubes containing 5 c.c. of air, and the whole were exposed for 34 days, under various conditions—i.e., in some cases light was admitted to the eudiometer only, and others were kept totally in the dark. The alterations in the volume of air were noted daily, with the following results:—Ordinary distillate under the influence of light took up all the air in 10 days; distillate refined with excess of soda required 11 days; ordinary petroleum, 12 days; oil refined with excess of acid and alkali, 34 days. The oil treated with excess of acid only, absorbed but two-thirds of the volume of air during the full period, and the sample previously exposed to light and afterwards refined over again had taken up barely any.—C. S.

IV.—COLOURING MATTERS AND DYES.

Toluene-azo-Phenols, Reduction of Ethers of. F. Düsterbehn, J. Klein, and G. Schkolnik. *Annalen*, 287, 161—183.

THE authors, continuing Jacobson's work (*Ber.* 26, 700) on the reduction of *p*-ethoxyazobenzene with stannous chloride and hydrochloric acid, which resulted in the discovery of the so-called "semidine" transformation, have examined the reduction products of the higher homologues, and certain of the compounds obtained, have formed the subject-matter of patents. The nomenclature employed is according to the following scheme:—

and a derivative of *o*-amido-diphenylamine is termed an *o*-semidine, whilst that of *p*-amido-diphenylamine is a *p*-semidine. In the case of *o*-toluene-azo-phenetol, the chief product is a *p*-semidine, 4-amido-3-methyl-4'-ethoxy-diphenylamine (*Ger. Pat.* 75,292, 1892) crystallising in needles melting at 82° C., whilst only small quantities of ultimate reduction products are obtained. With *m*-toluene-azo-phenetol, a mixture of *o*- and *p*-semidines and of other bases is obtained, whilst *p*-toluene-azo-phenetol gives principally decomposition bases, together with some *o*-semidine (*i.e.*, 2-amido-4' (or 5)-methyl-5 (or 4')-ethoxy-diphenylamine); and *p*-toluene-azo-phenol isobutyl ether, melting at 90° C., and the benzyl ether, melting at 128° C., give about 70—80 per cent. of decomposition products.

—T. A. L.

Toluene-Azo-Cresetols, Reduction of. E. Heber, F. Heinrich, C. Schwarz. *Annalen*, 287, 183—211.

THE six cresetols examined were prepared by combining the *o*- and *m*-cresetols with diazotised *o*-, *m*-, and *p*-toluidines and subsequent ethylation of the products obtained. On reduction, all the isomers give normal bases, and in addition either an *o*- or a *p*-semidine (see last abstract), or a mixture of the two; only the latter are here referred to. In addition to the melting points given, these compounds were further characterised by conversion into their formyl, acetyl, and thiourea derivatives, &c. 1. *o*-Toluene-*o*-azocresetol, melting at 36° C., gives a mixture of *o*- and *p*-semidines; the former, probably 2-amido-2',4-dimethyl-5-ethoxy-diphenylamine, melts at 78° C., whilst the latter melts at 86° C., and is 4-amido-2',3-dimethyl-4'-ethoxy-diphenylamine. 2. *m*-Toluene-*o*-azocresetol, melting at 47° C., gives an *o*-semidine melting at 91° C., which is probably 2-amido-3',4-dimethyl-5-ethoxydiphenylamine, whilst the *p*-semidine formed simultaneously, is 4-amido-2,3'-dimethyl-4'-ethoxy-diphenylamine, melting at 100° C. 3. *p*-Toluene-*o*-azocresetol gives an *o*-semidine, which is probably 2-amido-4,4'-dimethyl-5-ethoxy-diphenylamine, and melts at 76° C. 4. *o*-Toluene-*azo-m*-cresetol (melting point 64° C.) gives 4-amido-2',3-dimethyl-4'-ethoxy-diphenylamine, a *p*-semidine melting at 86° C. 5. *m*-Toluene-*azo-m*-cresetol, melting at 73° C., behaves similarly, giving a *p*-semidine melting at 96° C., which is 4-amido-2',2-dimethyl-4'-ethoxy-diphenylamine. 6. *p*-Toluene-*azo-m*-cresetol (melting point 64° C.) gives a very small quantity of an *o*-semidine, which was characterised by conversion into a stilbazonium base, $C_{30}H_{23}N_2O_2$, forming yellow needles melting at 179° C.—T. A. L.

m-Xylene-*azo*-Cresetol, Reduction of. G. Schkolnik. *Annalen*, 287, 211—212.

THIS compound was prepared by ethylating the oxy-azo-derivative obtained by combining diazotised xylylidine ($CH_3:CH_3:NH_2 = 1:3:4$) with phenol, which melts at 134° C., whilst the ethylated product melts at 97° C. The reduction products consist chiefly of xylylidine and phenetidine.—T. A. L.

Azophenetols, Reduction of. F. Meyer. *Annalen*, 287, 212—220.

THESE substances were obtained by diazotisation of the three phenetidines, combination with phenol, and subsequent

ethylation of the products. On reduction, they behaved similarly to the ethers of the toluene-azo-phenols described above, and the products obtained were characterised in a similar manner. 1. *o*-Phenetol azo-*p*-phenetol, melting at 78° C. (the corresponding phenol melts at 131° C.), gives, on reduction, principally a *p*-semidine, 4-amido-3,4'-diethoxy-diphenylamine, melting at 81.5° C., together with *o*- and *p*-phenetidine. 2. *m*-Phenetol azo-*p*-phenetol, the ether of the phenol melting at 106° C., melts at 71° C., and is converted on reduction for the greater part into a mixture of an *o*- and a *p*-semidine. With regard to the third isomeride, the combination of *p*-phenetidine (amidophenetol) with phenol has been described in *Ger. Pat.* 48,543, as a raw material for the manufacture of dyestuffs and phenacetin. It melts, however, at 126° C., and not at 104.5° C. The ethyl ether on reduction gives about 95 per cent. of *p*-phenetidine.

—T. A. L.

Corallin and Magenta, Chemistry of. K. Zulkowski. *Monatsh. für Chem.* 16, 358—493.

THE author arrives at the following conclusions:—

(1.) Certain colouring matters and other compounds of a phenolic character can be precipitated from their alkaline solutions by CO_2 , and this forms a ready means of assisting their purification. Such substances are Aurin, Rosolic acid, Phenolphthalein, &c.

(2.) Corallin, when prepared from pure phenol, contains, in addition to Aurin, two colouring matters of the formulae $C_{20}H_{16}O_4$ and $C_{22}H_{16}O_5$, which appear to stand in no definite relation to one another, and also two isomeric colourless substances of the formula $C_{10}H_{14}O_4$, *i.e.*, they contain one atom of oxygen more than Aurin, and may be designated α - and β -Aurin oxides.

(3.) Corallin, prepared from a mixture of phenol and cresol, contains all the above substances and in addition others, some of which appear to form a homologous series, but show no close relationship with Aurin. These are $C_{22}H_{20}O_4$ (Rosolic acid), $C_{22}H_{18}O_4$, $C_{20}H_{16}O_4$, and $C_{20}H_{16}O_5$, and may be called Rosolic groups.

(4.) By diazotisation of magenta free from para-magenta, there are formed several substances very similar to the above constituents of Corallin, and probably homologous with them. Such are $C_{23}H_{22}O_4$ (methylrosolic acid) and $C_{23}H_{20}O_4$.

The constitution of the triphenylmethane colouring matters, including Magenta and Corallin, is as yet but very imperfectly understood.—R. B. B.

Paranitrodiazobenzene Red. Oesterr. Wollen- und Leinen-Ind. 1895, 15, 401.

THE firm "Fabrique des Produits Chimiques de Thann et de Mulhouse," has again introduced paranitrodiazobenzene Red in consequence of the disuse of Mulhouse Red and Grenade. The fastness to light and to washing leaves much to be desired, but in this respect it compares favourably with its predecessor. The prepared colour keeps only a few hours in a cold room (without ice-cooling). The material is padded with a mixture of 400 grms. of β -naphthol, 400 grms. of soda solution of 40° B., $\frac{1}{2}$ litre of 50 per cent. Turkey-red oil, and 15 litres of water, dried in the hot flue, and immediately developed in a bath prepared as follows:—750 grms. paranitrodiazobenzene are mixed with 2 litres of water, and, after standing for half an hour, a solution of 60 grms. sodium acetate in 1 litre of water is slowly added, and the whole then diluted to 15 litres. Then follows washing in the open width, and soaping for half an hour in a vat containing 1 kilo. of soap and 1 kilo. of castor-oil soap in 700 litres, finally washing and drying. In printing with this colour, the material is padded with a mixture of 500 grms. β -naphthol, 500 grms. soda solution of 40° B., $\frac{1}{2}$ litre Turkey-red oil, and 12 litres water, dried in the hot flue, and printed with 560 grms. paranitrodiazobenzene powder, $4\frac{1}{2}$ kilos. dextrin-thickening, 50 grms. of sodium acetate, and $\frac{1}{2}$ litre turpentine, mixed cold. This mixture keeps sufficiently long (8—10 hours) at a temperature of about 30° C., so that no cooling is necessary. After printing, the goods are passed through soda and soap. The effects are equal to those obtained with paranitraniline, but the fastness to soap is poor. The paranitrodiazobenzene should be preserved in

the form of its compound with α -naphthylamine monosodium sulphamate, from which hydrochloric acid liberates the diazo-compound ready for use.—A. C. W.

Metanitraniline, Alkaline Reduction of. R. Mehlola and E. R. Andrews. *Proc. Chem. Soc.* 1895, [157], 214—215.

On heating an aqueous solution of metanitraniline with alkaline reducing agents, such as sodium stannite, the azoxy-compound—

separates out on cooling. It forms yellow scales (from toluene) or needles (from boiling water or dilute alcohol), m.p. 146—148°. The diacetyl derivative (m.p. 251°), the disazimide (m.p. 86—85°), the disazo- β -naphthol derivative (m.p. 214°—245°), and the metadiiodoazoxybenzene (m.p. 118—119°) have been prepared from the diamidoazoxy-compound. The corresponding azo-compound, having the constitution—

has been prepared by the complete reduction of the azoxy-compound to a hydrazo-compound by the action of zinc dust and alkali, and subsequent reoxidation. This has been found the most effective way of obtaining the azo-compound in a state of purity. It consists of dull orange needles when crystallised from boiling water, m.p. 150°—151°. The diacetyl derivative (m.p. 272°), the dihenzoyl derivative (m.p. 281°—285°), the disazo- β -naphthol (m.p. 282°), and the oxalate of the base have been prepared, and are described in the paper. The constitution was confirmed by conversion into the metadiiodoazobenzene (m.p. 150°—151°) of Gabriel (*Ber.* 1876, 9, 1410). Both the azoxy- and azo-compounds are well-characterised bases forming diacid salts.

PATENTS.

Azo-Dyes, Improvements in the Manufacture of, and in the Production of Black Shades on Cotton or other Vegetable Fibre, or on Silk. J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 1002, Jan. 15, 1895.

The azo dyestuffs prepared by combining diazo compounds with 1,1',4 or 1,1',4'-amido-naphthol sulphonic acids (Eng. Pat. 7713 of 1891; this Journal, 1892, 514) have always contained a quantity of disazo dye, rendering the product impure. According to the present invention, these compounds can now be obtained in a pure state, and a method is also given for employing them in the production of dark green, or blue to black shades, on cotton or other vegetable fibre, or on silk. The improvement in the combination consists in carrying out the process in presence of an excess of a mineral acid and without the use of sodium acetate. This is more especially the case with the diazo compounds from aromatic amines containing substituting nitro or halogen groups, but the same precaution is necessary with α -naphthylamine, as the following example shows. About 286 kilos. of α -naphthylamine and 780 kilos. of 30 per cent. hydrochloric acid are diazotised in the usual manner with 140 kilos. of sodium nitrite and made up to 1,200 kilos. with sufficient water and ice. The diazo solution, which then contains 0.6 per cent. of free hydrochloric acid, has added to it 530 kilos. of 1,1',4-amidonaphthol sodium sulphamate in 10,000 litres of water. The mixture must be well stirred, and must react strongly acid to Congo-paper the whole time, until the whole of the diazo compound has been taken up, the dyestuff being finally separated in the usual way. The process for obtaining deep blacks consists in printing or padding the goods with a mono-azo dyestuff obtained from an amido-naphthol sulphonic acid, as

described, and subsequently developing them by immersion in a suitable diazo-solution. For instance, to obtain a black on cotton, the goods are padded with the azo-dyestuff from *p*-dichloro-aniline and 1,1',4'-naphtholsulphonic acid, and, so prepared, are worked in a solution containing about 1 per cent. of tetrazo-ditolyl acetate until a test portion of the material does not turn violet on immersion in hot 2 per cent. sodium carbonate solution. The goods are then washed, first with water, and subsequently with a hot solution of an alkaline soap in order to remove the second diazo group in the tetrazo-ditolyl, which does not react.—T. A. L.

New Basic Colouring Matters, The Manufacture and Production of. J. Y. Johnson. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 1352, Jan. 19, 1895.

These new colouring matters, which appear to belong to the acridine series, are obtained from certain substituted auramines by heating their hydrochlorides together with *m*-phenylene or *m*-tolylene diamine, either with or without a condensing agent, such as zinc chloride. The most suitable substituted auramines are the *m*-amidophenyl- and *m*-amido-tolylauramine, which may be regarded as derivatives of *m*-phenylene and tolylene diamine, and of tetramethyl or tetra-ethyl-diamidodiphenylmethane. About 40 kilos. of tetra-methyldiamidobenzophenone, 27 kilos. of *m*-phenylene-diaminedihydrochloride, and 9 kilos. of *m*-phenylenediamine are heated, with constant agitation, from 195° to 215° C. When a sample dissolved in dilute hydrochloric acid and boiled, retains its brownish-yellow colour, and no further increase in the amount of colour is produced by this treatment, the melt is allowed to cool and subsequently dissolved in 400 litres of boiling water and 20 kilos. of 30 per cent. hydrochloric acid. After cooling and filtering, the colouring matter is precipitated by adding salt and zinc chloride. The precipitate is filtered off, mixed with 20 kilos. of hydrochloric acid, and dried on the water-bath, when it forms a readily soluble salt. The colouring matter gives a brownish-yellow solution with a greenish fluorescence. It dyes cotton mordanted with tannin, and also gives brownish-yellow shades on leather.—T. A. L.

Alpha-amido-alizarin-sulphonic Acid, Manufacture of. O. Imray, London. From "The Farbwerke vormals Meister, Lucius, and Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 1392, Jan. 21, 1895.

ONE part of α amido-alizarin is stirred into 10—15 times its weight of fuming sulphuric acid, containing 20—40 per cent. of anhydride, and heated at 100—140° C., until a sample dissolves, when boiled with water, to a bright carmine solution. After cooling, the melt is poured on to ice, and the whole is boiled until the characteristic red-coloured solution is obtained, when, after filtering, the sulphonic acid is separated by salting out with potassium or sodium chloride. The sulphonic acid is then washed till neutral, and dried, when it forms a blackish-brown powder, easily soluble in water to a carmine solution. It is an acid and also a mordant colouring matter, and dyes wool bluish-red from an acid bath, whilst it gives prune shades on a chrome mordant. It has been found that the first action of fuming sulphuric acid on α -amido-alizarin is the formation of an intermediate product sparingly soluble in cold water, which, on boiling with water or dilute acids, is converted into the α -amido-alizarin sulphonic acid. This intermediate product has probably the constitution of a sulphuric ether or of a sulphamic acid.—T. A. L.

Colouring Matters, Improvements in the Manufacture of [Red Basic Cotton Dyes]. H. H. Lake, London. From A. Leonhardt and Co., Mühlheim-on-the-Maine, Germany. Eng. Pat. 1414, Jan. 21, 1895.

THE process consists in alkylating the orange-red dyestuff obtained from formaldehyde and *m*-amido-*p*-cresol—

(Eng. Pat. 12,323 of 1893; this Journal, 1894, 722). Similar products are obtained by carrying out the process described in Eng. Pat. 13,217 of 1889 (this Journal, 1890, 934) by using formaldehyde and an alkylated *m*-amido-

p-cresol. The alkylation, according to the first process, is effected by means of ethylbromide in spirit at about 130°–140° C. for three hours, the colouring matter, after distilling off the spirit, being precipitated with salt. According to the second method, 15 kilos. of ethyl-*m*-amido-*p* cresol, 13 kilos. of 30 per cent. caustic soda lye, and 300 litres of water, are mixed with 3.7 kilos. of a 40 per cent. formaldehyde solution, the whole after some time being raised to the boil. When the formaldehyde has disappeared, a small quantity of acetic acid is added to precipitate impurities, and, after filtering, the diethyldiamidodihydroxyditolylmethane, which melts at 169° C., is precipitated by more acetic acid. In order to convert this product into the corresponding colouring matter, 1 kilo. is added to 3 kilos. of concentrated sulphuric acid, and the whole is heated on the water-bath until a complete solution is obtained. After some hours, dehydration is complete, and each kilo. of the melt is poured into 2 litres of water and 2 kilos. of brine, and oxidised at 90° C. by adding 1.3 kilos. of a ferric chloride solution of sp. gr. 1.14. The colouring matter separates as a crystalline precipitate, and is filtered off, washed with brine, and pressed. The colouring matters obtained by either of these processes are suitable for dyeing and printing on cotton, and give redder shades than those hitherto known.—T. A. L.

Para-amido-benzyl Alcohol, Improvements in the Manufacture and Production of, and Homologues and Analogues thereof and Derivatives therefrom. G. W. Johnson, London. From Kalle and Co., Bielefeld-on-the-Rhine, Germany. Eng. Pat. 1963, Jan. 28, 1895.

THE product referred to is obtained by the reduction of *p*-nitrobenzyl chloride in neutral or alkaline solution by means of ferrous hydrate or zinc dust. The new substance, which is entirely different from the *p*-amidobenzyl alcohol described by G. and O. Fischer (Ber. 24, 723), melts at 65° C., crystallises from benzene, and has the formula $H_2N \cdot C_6H_4 \cdot CH_2OH$. It possesses the properties of a primary amine and combines with benzaldehyde, formaldehyde, and benzoyl chloride, and can be diazotised, the diazo solution also combining with the undiazotised base to form a diazo-amido compound. When the new base is boiled with a small quantity of hydrochloric acid in aqueous solution, it is converted into an anhydride, and this substance can be obtained directly by reduction of the nitro compound by means of zinc dust in an acid solution. It can also be prepared, as well as its analogues and homologues, by the action of formaldehyde on aniline, *o*-toluidine, methyl- or ethylaniline, methyl- or ethyl-*o*-toluidine, *o*-anisidine, or *o*-amidophenetol by employing equimolecular proportions in presence of a mineral acid. When formaldehyde is employed, the anhydro derivatives of the amido bases may be made first, and subsequently transformed. About 30 kilos. of anhydroformaldehyde aniline are dissolved in 150 kilos. of strong hydrochloric acid. The new product gradually crystallises out, and, after dissolving in 500 litres of water, the whole mass is neutralised with caustic soda lye and the precipitated base is filtered off and washed. The following is another method employed:—A solution of 130 kilos. of aniline salt in 600 litres of water, is mixed, cold, with 25 kilos. of a 40 per cent. formaldehyde solution and allowed to stand until the whole is converted into a yellowish crystalline mass, when, after precipitation with soda lye, the free amido-benzyl alcohol is washed and dried.—T. A. L.

Colouring Matters, The Manufacture or Production of [Basic Reds]. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 2041, Jan. 29, 1895.

THIS is an extension of Eng. Pat. 9610 of 1894 (this Journal, 1895, 478), describing further processes for producing azine dyestuffs from phenylated or tolylated *m*-tolylene diamine (e.g., $CH_3:NH_2:NHC_6H_5 = 1:2:4$) by heating the azo derivatives of these substances in a suitable solvent together with primary, secondary, or tertiary amines of the benzene or naphthalene series. A further method is to oxidise these latter amines together with phenyl-triamidotoluene ($CH_3:NH_2:NHC_6H_3:NH_2 = 1:2:4:5$) or with *p*-

tolyl-triamidotoluene ($CH_3:NH_2:NHC_6H_2:NH_2 = 1:2:4:5$) in presence of suitable solvents or diluents:—5.7 kilos. of the azo compound from diazotised *p*-sulphanilic acid and phenyl-*p*-amido-*o*-toluidine, 1.4 kilos. of α -naphthylamine, and 20 kilos. of phenol are heated together, with agitation, at 90°–110° C. until the melt turns a pure red. An excess of hot dilute soda lye is then added, and, after cooling, the separated dyestuff is filtered off. In order to purify it, the press cake, after dissolving in hot water and filtering, is salted out with hydrochloric acid. The colouring matter so obtained is easily soluble in water, and dyes tanned cotton bright bluish-red shades. It is identical with the dyestuff obtained by the interaction of benzene-azo- α -naphthylamine and phenyl-*p*-amido-*o*-toluidine, according to Eng. Pat. 9610 of 1894. The following is another method for producing the same substance:—2.2 kilos. of phenyl-triamidotoluene (melting at 134° C. and obtained by reducing the azo compound from diazotised *p*-sulphanilic acid and phenyl-*p*-amido-*o*-toluidine), 1.8 kilos. of α -naphthylamine hydrochloride, and 20 kilos. of phenol are heated on a water-bath with free access of air until the melt turns a pure red. The dyestuff is then isolated according to the method already described.—T. A. L.

Colouring Matters Containing Sulphur, Manufacture of [Cotton Browns and Yellows]. J. Imray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis," Paris, France. Eng. Pat. 3414, Feb. 16, 1895.

THESE colouring matters are produced by the action of sulphur, or sulphur and alkaline sulphides, on acetylated diamines, or the corresponding acetyl nitramines. A mixture of 100 kilos. of acetyl-*p*-phenylene diamine and 200 kilos. of sulphur is heated for three hours to 200°–250° C. When the reaction has moderated, and the evolution of sulphuretted hydrogen has ceased, the melt is allowed to cool. The colouring matter so obtained is soluble in hot alkaline sulphides and dyes cotton directly a brownish-yellow. A yellow colouring matter for cotton is produced by heating to 300° C. for 3–4 hours a mixture of 100 kilos. of diacetyldinitro-benzidine, 100 kilos. of dry sodium sulphide, and 200 kilos. of sulphur until the reaction is complete. The product is soluble in water, alkaline sulphides, sulphites and bisulphites, but insoluble in acids. The new colouring matters are stable to ordinary reducing agents. In order to obtain bright shades, the dyed material should be passed through an oxidising bath—bichromate, ferric chloride, or an alkaline hypochlorite. The new products are termed "thioatechines," and when precipitated from their solution in soda or sodium sulphide by dilute acids, a paste is obtained which, on prolonged contact with alkaline sulphites or bisulphites, becomes soluble, and may be used directly for dyeing, or, after thickening, for printing.

—T. A. L.

Azo Dyes, Manufacture of [Blue-Blacks]. J. Imray, London. From "The Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 3515, Feb. 16, 1895.

ACCORDING to Eng. Pat. 7713 of 1891 (this Journal, 1892, 514), colouring matters are obtained by combining two molecular proportions of a diazo compound with one molecular proportion of 1.1'.4-amidonaphthol sulphonic acid of Eng. Pat. 9676 of 1890 (this Journal, 1891, 538), or with the 1.1'.4'-acid obtained by fusing with caustic alkali the naphthylamine disulphonic acid prepared by sulphonating the naphthylamine sulphonic acid 8 of Ger. Pat. 40,571. The methods hitherto employed have been to effect the combination either in an alkaline solution throughout, or else to perform the first part of the operation in an acid solution and the second in an alkaline one. The patentees have discovered that much more valuable products are obtained by carrying out the second combination in a faintly acid solution, the following being a typical example:—The diazo solution from 15 kilos. of α -naphthylamine is poured into an alkaline solution of 1.1'-amidonaphthol sulphonic acid. When the formation of the azo compound is complete, the solution is acidified with acetic acid and *p*-diazobenzene sulphonic acid from 19.5 kilos. of sulphanilic acid is stirred

is. After the combination is complete, the colouring matter is salted out, pressed, and dried. It dyes wool a greenish blue-black from an acid bath, whilst the combination with the same components carried out according to Eng. Pat. 7713 of 1891 gives violet-blue shades on wool.—T. A. L.

Azo Dyes, Manufacture of [Wool Blue-Blacks]. J. Imray, London. From "The Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 3416, Feb. 16, 1895.

It has been discovered that under certain conditions, 1.1'.4-amidonaphthol sulphonic acid will combine with three molecular proportions of a diazo compound, and, according to the components employed, varying tints and various degrees of solubility of the resulting dyestuffs may be obtained. The combination with the third component must be carried out in a faintly acid solution, and whilst this is an advantageous condition for the second combination, the first may take place in an alkaline solution. The diazo solution from 15 kilos. of α -naphthylamine is run into an ice-cold alkaline solution of 24 kilos. of 1.1'.4'-amidonaphthol sulphonic acid. After the combination is complete, acetic acid is added, and the same quantity of α -diazonaphthalene is run in. When the whole of the diazo compound has been taken up, the diazo compound from 24.5 kilos. of sodium naphthionate is added, sufficient free acetic acid always being present. After 2—3 days the whole is heated and the colouring matter salted out, filtered, and dried. It dyes wool blue-black from an acid bath.—T. A. L.

Compounds designed for Dyeing and Printing, Improvements relating to the Manufacture of. "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis," St. Denis, and R. Vidal, Paris, France. Eng. Pat. 3612, Feb. 19, 1895.

The colouring matter "Laval Catechu," obtained by the action of sulphur and alkalis on various organic substances, and the dyestuffs produced from disubstituted aromatic compounds by the same reaction, according to Eng. Pat. 19,880 of 1893 (this Journal, 1894, 941), have all similar properties. They are all insoluble in the usual solvents and in dilute acids, but dissolve easily in alkalis and alkaline sulphides with a bottle-green colour, and dye unmordanted vegetable fibres very fast shades. In order to obviate the use of alkaline sulphides, the patentees have discovered that these substances can be rendered soluble by treatment with alkaline sulphites or bisulphites. For instance, the product obtained by the action of p -amido-phenol on sulphur and caustic soda at 180°C . is precipitated from its alkaline solution with dilute hydrochloric acid. The damp product, after filtering, containing about 15—20 per cent. of dry substance, is treated with crystallised sodium sulphite in the proportion of 45—60 kilos. of the salt to 100 kilos. of the paste. In about three days, complete solution is effected, and the product may be used in this form or dried down for convenience of transport.

—T. A. L.

New "Coupled Tetrazo Compounds," Manufacture of, and of Complex Poly Azo Colouring Matters resulting therefrom [Cotton Blues and Blue-Blacks]. O. Imray, London. From "The Society of Chemical Industry in Basle," Basle, Switzerland. Eng. Pat. 14,483, July 30, 1895.

The "coupled tetrazo compounds" are obtained by combining two molecular proportions of the same or of different tetrazo compounds with one molecular proportion of a component capable of so combining—as, for example, dihydroxy-naphtho-sulphonic acid (Eng. Pat. 14,161 of 1892; this Journal, 1893, 597), dihydroxy-naphthalene sulphonic acid G, 1.1'.3.3'-dihydroxy-naphthalene disulphonic acid, 1.1'.3.3'-amidonaphthol disulphonic acid, tolylene diamine sulphonic acid—

2.3.3'-amidonaphthol sulphonic acid, &c. The compounds so produced have the general formula—

where P is the radicle of a p -diamine and R is one of the components above alluded to. The compound so obtained can be further combined with two similar or different amines or phenols, or their derivatives. The following example illustrates the method employed:—The tetrazo compound from 18.4 kilos. of benzidine is poured into a cold alkaline solution of 16 kilos. of sodium 1.1'.3.3'-amidonaphthol disulphonate. The intermediate compound, which contains two free diazo groups, separates in black flakes. After standing 2—3 hours, the whole is added to an alkaline solution of amidohydroxy-naphtho-sulphonic acid and allowed to stand 12 hours, when, after heating, the colouring matter is salted out, filter-pressed, and dried. It dyes violet-black shades on unmordanted cotton, and, after diazotisation and development on the fibre with m -phenylene diamine, gives deep black shades. The following process yields a blue for cotton:—The tetrazo solution from 9.2 kilos. of benzidine is run into a cold solution of 16 kilos. of amidonaphthol disulphonic acid in presence of sodium acetate. After making the mixture alkaline, the tetrazo solution from 10.6 kilos. of tolidine is added to it. The formation of the intermediate product is complete in about 3—4 hours, and a solution of 32 kilos. of 1.1'.3.3'-amidonaphthol disulphonic acid is then added, the colouring matter finally being separated in the usual manner.

—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

Paper Sails. J. Soc. Arts, 1896, 44, 146.

PAPER sails as used in the United States are said to be much cheaper than canvas sails, and it is affirmed that by special treatment of the materials they can be made as soft, flexible, and untearable. Bichromate of potassium, glue, alum, a solution of alkaline silicate and fat are added to the paper pulp, and a fairly thick paper is produced from this by means of a paper-making machine. Two strips of this are then pasted together, and passed through rollers under considerable pressure, the paper then being in the form of very thin, soft sheets. It is then passed, in an endless roll, through a weak solution of sulphuric acid, which converts the upper surface into a kind of parchment. The subsequent processes are washing with soda solution, dyeing, and glazing. In the manufacture, care is taken, when the strips of paper are fastened together, to leave the edges free, so that other strips can be added at the sides, and a sufficient breadth for sails thus formed. The paste which is used for fastening the strips together contains the same ingredients as those added to the paper pulp. The edging of the sail is formed by inserting cords or ribbons at the sides.

Singeing Fabrics. E. Schweitzer. Färber Zeit. 1895, 6, 309—311.

POIRRIER (Bull. Soc. Ind. de Reims, 1878) has shown that goods which have been well singed take up a deeper colour than unsinged or slightly singed fabrics; therefore if the singeing is not regular, flecks result. The use of bronze instead of iron plates for singeing goods is recommended, and the plates are preferably corrugated.

Gas-Singeing.—The chief objections to the older forms of gas-singeing machine (Tulpin) were (1) The production of streaks of more or less partially singed fibre between the various burners; (2) The production of flecks by sudden lighting of the flames. Tulpin's machine has been improved by various engineers, but two or three years ago, Descat-Leleux devised a form which gives a very accurate and regular result. In a metal case of hexagonal section, provided with a slit 6—8 mm. in diameter, coal-gas and compressed air, in the proportions necessary to form a non-luminous flame, are mixed and allowed to burn at the opening, which runs along the whole breadth of the machine. The whole arrangement is so contrived that it can be instantly removed from action on the fabric should a stoppage of the machinery occur. The length of the singeing surface can of course be modified by simply closing part of the slit, and the intensity of the flame is increased or diminished by regulating the supply of compressed air or of the gas. In order to prevent the smouldering

or burning of the goods by any sparks they may carry off, it is only necessary to pass them through damped rollers or into a steam-chest. The fabric, when passing through such a gas-singeing machine as that described, does not become heated, as a whole, to more than 100°C . and so long as there are no salts present which decompose at this temperature, it is in no way injured.—H. I.

VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

New Mechanical Dye-Vat. E. Müller. Färber Zeit. 1895, 6, 345—346.

A wool dye-vat is described which differs from the ordinary form. There are two tanks, one inside the other, separated by a space of about 5 cm. in width. The inner vessel is perforated with small holes. Above both vessels runs the reel or winch, provided with blades which dip into the vat, and the liquors are heated by a steam-pipe in the space between the two vessels. In emptying the vat, the winch is raised by chains attached to a beam above and the vat tilted forwards, the wool being received on hooks. The author states that he has found these vats both economical of labour and as regards expense.—H. I.

Vegetable Colouring Matters, Behaviour of, towards Ammonium Persulphate. G. Eberle. Färber Zeit. 1895, 6, 512—514.

THE author examined the behaviour of logwood blacks and catechu brown matters towards ammonium persulphate, $(\text{NH}_4)_2\text{S}_2\text{O}_8$. This substance loses oxygen on heating to 70°C . in aqueous solution and forms ammonium sulphite. Logwood extract is turned yellow at ordinary temperatures by this substance, and on heating with excess, it is completely bleached. Fustic extract becomes darker in shade, and on cooling deposits a yellow-brown powder.

On dyeing hanks of cotton-yarn in American logwood extract (10 per cent. of the weight of the cotton), and fixing by means of a 2 per cent. bath of copper sulphate, it was noticed that the colour darkened 10 per cent. during the dyeing, mordanting, and drying processes; the colourless hæmatoxylin copper compound changing into the coloured hæmatein lake.

If the hanks be brought, immediately after the drying and fixing process, into a cold solution of 5—1 per cent. of ammonium persulphate, an instantaneous darkening of the colour is produced, which is more permanent the smaller the amount is of ammonium persulphate present; $\frac{1}{2}$ to $\frac{1}{4}$ per cent. will suffice, on heating, to change the colour of copper hæmatoxylin lake into a blue-grey and finally into a brown (colours often noticed in old blacks).

American fustic extracts of a pure yellow-brown are preferable to those of a red-brown colour. The former give on alumina- and chrome-mordanted cotton a vivid yellow or

olive colour, whilst the latter give a dull reddish-yellow tone. The clear yellow fustic extract, on heating in contact with air for some time, is changed into the other variety. If cotton dyed with the former extract (10 per cent.) and 2 per cent. of alum, be treated with 1—8 per cent. of ammonium persulphate, colours resembling these obtained from the red-yellow extract are obtained. The intensity of the colour of wool dyed with fustic extract (5 per cent.) and bichrome is reduced 10 per cent. by persulphate (1 per cent.). The extract-maker should therefore take care that his liquors are as much as possible excluded from the oxidising action of the air in evaporating down. Cotton hanks (10 grms.) were heated for $\frac{1}{2}$ hour in a solution of catechu, and, after cooling, taken out of the bath. The hanks were treated with ammonium persulphate, 15—22 per cent., and gradually heated; at 70° the colour began to appear, and at 90° a yellow shade was produced. After heating $\frac{1}{2}$ hour, the hanks, on drying, had a pure yellow-brown colour such as has not been previously obtained with catechu. That the bichrome-dyed catechu fabric contained chromium as a lake-forming agent was rendered probable by the fact that the persulphate-dyed catechu yellowish-browns are changed into the characteristic bichrome catechu browns by treatment with chromic salts. Curiously enough, the bichrome catechu browns are converted into yellowish-brown by the action of ammonium persulphate.—H. I.

The Dyeing Process, The Nature of. The Distribution of Methylene Blue between Water and Mercerised Cellulose. G. v. Georgievics and E. Löwy. Monatsh. für Chem. 16, 345—350.

AS stated by one of the authors in a previous paper (this Journal, 1895, 653), a larger proportion of colouring matter is taken up by fibres from dilute than from concentrated solutions. If Cw be the amount of dyestuff in 100 c.c. of dye-liquor after the process, and Cf the amount of colour taken up by 100 grms. of fibre, it would appear that the

distribution of colouring matter follows the law $\frac{\sqrt[3]{Cw}}{Cf} =$

constant. In the former paper was ascertained the value of this constant in the case of indigo extract dyed upon silk, and further researches have been made to discover how far the value of the law depends on the chemical nature and physical structure of the dyed material. With this object, the behaviour of cellulose in the two forms of fibre and powder has been studied. If cotton is precipitated from its solution in ammoniacal copper hydrate by an acid, the precipitated cellulose contains much hydrocellulose, which has a greater affinity for basic colouring matters than cotton. In order to obtain materials of more similar composition, both were subjected to mercerisation. After this treatment, the proportion of water in each was:—Mercerised cotton, 10.08 per cent.; mercerised cellulose in powder, 15.25 per cent.

Dyeing took place at a temperature of 14° — 17°C ., and a series of experiments was made similar to those described in the previous paper, each trial being repeated at least twice. The result gave in each case a constant value for

the ratio $\frac{\sqrt[3]{Cw}}{Cf}$. The law $\frac{\sqrt[3]{Cw}}{Cf} = \text{constant}$, holds good

therefore for cotton as well as silk, and f may represent material of other than fibrous structure. The actual value,

however, of the constant $\frac{\sqrt[3]{Cw}}{Cf}$ is greater for mercerised

cotton than for mercerised precipitated cellulose, i.e., the latter would appear to have taken up more colouring matter than the former. This appears to contradict results of former experiments (this Journal, 1894, 945), but the difference depends entirely on the temperature at which dyeing takes place. At 100°C . the powdered form takes up much less colour than the fibrous; at low temperatures the reverse is the case. In the latter case, the increased attraction is due to the greater surface area of the powdered cellulose, but owing to this same cause the powder offers less resistance to the increased solvent power of the water at high temperatures, and thus loses colour more readily than the fibre.

In all the above results, the author perceives confirmation of his view that the dyeing operation is due to "surface-effects" or "absorption-phenomena" similar to the absorption of gases by carbon, &c., and rejects the chemical theory and "solid solution" in favour of "mechanical affinity."—R. B. B.

Colours on Cotton, Fading of. W. N. Ogloblin. J. russ. phys. Ges. 1895, 27, 80.

SAMPLES were exposed to sunlight in (1) Air, (2) Dry carbon dioxide, (3) Moist carbon dioxide. In the latter indifferent gas, the fading was greater in the presence of moisture, but was far greater in damp air. The action of red, yellow, green, blue, and violet light on the coloured fabric was investigated by exposing it covered with glasses of these colours. The colours fade most completely in light which is most nearly of the colour complementary to their own.—A. C. W.

Trades Waste, Treatment of. W. Naylor. Proc. Inst. Civil Eng. 1895, 123, [Part 1.].

PATENTS.

Thickeners or Vehicles for Colours, Mordants, and the like, Improvements in and relating to. W. W. Horn, London. From W. Maybury, Los Angeles, California, U.S.A. Eng. Pat. 22,276, Nov. 17, 1894.

THE application is claimed of the mineral, known as soap-rock, as a thickening, filling, or finishing agent for textile tissues, yarns, and paper, and as a thickening agent for tissue and paper printing.

The mineral in question is largely found in New Zealand and the Western States of North America. It has approximately the following percentage composition:—Silica (64.76 parts), alumina (16.87), ferric oxide (4.62), magnesia (3.45), lime (trace), phosphoric acid (1.22), water (5.01), and grit and dirt (1.63).

It is prepared for use by breaking or grinding into small pieces and washing with dilute hydrochloric acid (1° Tw.) or alum solution (0.5° Tw.), to remove part or all of the iron and water. The washed clay is then left for three to five days in contact with five times its weight of water, by which time it will have formed a "fine, plastic paste of a greasy nature," which can be further thinned with water if desired. The paste thus obtained is, lastly, strained to remove the grit it contains.

As a thickening agent, soap-rock is stated to possess the following advantages, amongst others, over organic thickening agents:—It is not liable to be attacked by mildew or to ferment; it does not become thin in time; and it is unaffected by oxidising agents, such as potassium permanganate and chromic acid, and can therefore be employed to thicken solutions of them.—E. B.

Machinery for Dyeing Loose Cotton, Wool, and other Fibres, Improvements in. E. Heppenstall and E. Sykes, Turbridge. Eng. Pat. 693, Jan. 11, 1895.

THE improvements relate to the dyeing machine devised by Weldon (Eng. Pat. 18,973 of 1889; this Journal, 1890, 175), and consist in causing the dye-liquor to circulate by means of a centrifugal pump. The liquor enters the vat at the bottom and is distributed through perforated branch-pipes into the vat. Thence it is drawn, either from the top or the bottom, back to the pump. Finally, when the dyeing is completed, it is run into the drain or is pumped into a storage-tank for use again.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Potassium Chlorate, Manufacture of. K. J. Bayer. Chem. Zeit. 1895, 19, 1453—1455.

By the method hitherto employed in the manufacture of potassium chlorate, only one-sixth, and frequently less, of the chlorine was obtained in the form of potassium chlorate, the remaining five-sixths being converted into calcium chloride, which is of practically no commercial value.

Although magnesia was substituted for lime with the intention of obtaining a marketable product in the chloride of magnesia, or otherwise to reconvert the same into chlorine or hydrochloric acid, this process was never very widely introduced, as the slight advantage gained was more than neutralised by the difficulty in manipulation, and expensive plant.

Better results, it is said, are obtainable if, instead of lime or magnesia, an oxide be used, like oxide of zinc, yielding a chloride, for which there is a large demand.

To carry out the process, chlorine is passed into zinc oxide suspended in cold water, when, as in the case of lime, at first oxychloride of zinc and hypochlorite of zinc are formed, the whole finally going into solution according to the equation, $2\text{ZnO} + 4\text{Cl} = \text{ZnCl}_2 + \text{ZnCl}_2\text{O}_2$.

The conversion of the hypochlorite into chlorate takes place quantitatively in the presence of the necessary potassium chloride, or if the potassium chloride be added to the zinc oxide at the beginning, the temperature being maintained at 90°—95° C.

These solutions are of about 30° B., and, in cooling, fairly pure crystals of potassium chlorate are obtained. On concentrating the mother-liquor to about 60° B., the greater part of the remaining potassium chlorate crystallises out, and the mother-liquor, now containing only very little potassium chlorate, is treated with hydrochloric acid and then evaporated to dryness to obtain the chloride of zinc.

The apparatus varies very little from that now in use for the manufacture of chlorate by the lime process; the evaporation of the zinc chloride solution being carried out in iron vessels, preferably in a vacuum, as traces of iron are not detrimental for most purposes.

The advantage claimed in this process is a better yield of chlorine as chlorate, and in obtaining the whole of the chlorine as a marketable product.

In the following, comparisons of the cost of production are made:—

According to K. Jurisch, the cheapest method of manufacturing chlorine is by the Hurter-Deacon process, and, taking this as a basis, the chlorine necessary for the production of 1,000 kilos. of potassium chlorate would cost M. 270.04, the total cost being M. 1,234.73 for 1,000 kilos. of potassium chlorate and 4,000 kilos. of zinc oxide.

The Hurter-Deacon process has only been chosen for the sake of comparison, and it is not the intention to use dilute chlorine for this process, but rather concentrated chlorine, obtained by a process which would probably be M. 50 per 1,000 kilos. potassium chlorate—cheaper than the Hurter-Deacon process.

The chloride of zinc which is obtained, is very pure, but may contain a little potassium chloride, which, however, would hardly be detrimental for manufacturing purposes.

By the lime process, according to K. Jurisch, the total costs for 1,000 kilos. of potassium chlorate amount to M. 800.70.

To compare the two processes, it is necessary to take half of the costs of manufacture for the potassium chlorate, and half for the chloride of zinc. We then find the cost for manufacturing 1,000 kilos. of potassium chlorate amounts to M. 617.36, as against M. 800.7 by the lime process, and the cost for manufacturing 4,000 kilos. of chloride of zinc, to M. 617.36, or for 1,000 kilos., M. 154.34.

At the present time it is hardly possible to make a comparison with the electrolytic chlorate of potassium, as too little is known about the cost. However, a comparison might be made by calculating the cost to produce chlorine in the electrolytic manufacture of caustic soda and bleaching-powder, as has been done by C. Häussermann. In this case, from the total cost of producing caustic soda and bleaching-powder, the lime, packages, &c., for bleaching-powder and the caustic soda are deducted.

This chlorine is sufficient for about 2,200 kilos. of potassium chlorate; therefore 1,000 kilos. would cost M. 307.84, or about 14 per cent. more than that obtained by the Hurter-Deacon process.

The total advantages gained are said to be as follows:—

1. A 25 per cent. cheaper production of potassium chlorate when compared with the lime process.
2. Obtaining chloride of zinc as secondary product.

3. Better yield of potassium chlorate.
4. Advantage of being able to manufacture sodium chlorate by substituting sodium chloride for potassium chloride.
5. From a sanitary point of view, the non-contamination of water with waste calcium chloride.—J. R.

Potassium Cyanide, Synthetic Methods of Manufacturing.
N. Caro. Chem. Ind. 1895, 13, 244—246; 14, 287—293.

The attempts to make potassium cyanide directly from its elementary components without the use of animal refuse as raw material, may be classified in three groups, viz.:

1. Methods in which ammonia and fire are used; 2. Those in which atmospheric nitrogen and fire are employed; and 3. Wet methods.

1. Manufacture of Potassium Cyanide by Ammonia and Heat.—These methods are dependent upon the old yellow prussiate process. Liebig was the first to show that the yellow prussiate of potash was not formed until the fused mass was lixiviated. On treating the fused mass with water, the potassium sulphide formed therein by reduction of the sulphate, dissolves iron readily, forming the double compound FeK_2S , which, in solution with potassium cyanide, yields potassium ferrocyanide. Liebig further assumed that part of the potassium combined with cyanogen to form potassium sulphocyanate, which in the presence of iron became desulphurised, yielding potassium cyanide.

Karmrodt in 1857 first proved the truth of Liebig's views, and also some other important facts, viz., that the best yield of yellow prussiate was obtained by the use of about 50 per cent. of carbonised horn, and that the ammoniacal gases which are evolved when raw animal matter is used in the operation only form small quantities of cyanogen. His experiments showed that when carbonate of ammonia was led over potash, only about one-fifth of the theoretical yield of cyanogen was obtained. He proposed to lead the ammoniacal gases from animal matter over red-hot carbon impregnated with potash, and in this way to save at least one-fifth of the cyanogen, which would be otherwise lost.

In recent times, Beilby (this Journal, 1892, 747 and 1004) has patented a process in which the materials are brought into intimate contact by adding to the mixture at the beginning 20 per cent. of potassium cyanide, by which the mass is rendered readily fluid, and is then allowed to drop from one sieve to another in a columnar apparatus, meeting at the same time an upward stream of ammonia.

Barr and MacFarlane (this Journal, 1893, 602) believe that the fixed alkali in these various processes only plays the part of a "contact substance," and that the formation of cyanide compounds is due to the reaction as stated by Langlois, $\text{CO} + 2\text{NH}_3 = \text{NH}_4\text{CN} + \text{H}_2\text{O}$.

Siepermann, however, has proved that the formation of alkaline cyanides can be produced by two distinct operations: by the action of ammonia upon potassium carbonate (which is mixed with barium carbonate in order to increase the surface exposure), and in the absence of carbon the products are potassium cyanate, water, and potassium hydrate, $\text{K}_2\text{CO}_3 + \text{NH}_3 = \text{KOCN} + \text{H}_2\text{O} + \text{KOH}$. If now the potassium cyanate be heated with carbon, potassium cyanide is formed. These two operations are reduced to one when, as is usually the case, alkaline carbonates are heated to redness with carbon in a stream of ammonia (H. Grüneberg, H. Flemming, and W. Siepermann. Eng. Pat. 13,697, 1889; this Journal, 1890, 860).

Looking at the above-described methods in the light of Siepermann's reactions, we draw the following conclusions, which have been fully confirmed in practice:—Karmrodt's process failed because the excess of potash in his mixture melted and surrounded the particles of carbon, thus preventing the reduction of potassium cyanate to cyanide. Beilby succeeded in producing a more intimate contact among his materials, but no substance could be found of which to make sieves and towers which would not be rapidly destroyed by the hot alkaline mixture; whilst the methods of Lucas and Johnson (in which charcoal or coke is impregnated with alkali) do not provide a sufficient

surface contact between the ammonia and the potassium carbonate; Siepermann's process arrives at this at the cost of making the mass infusible (viz. by the addition of barium carbonate). The experience that has been gained with this last process seems to show that with suitable apparatus, e.g., a revolving furnace, the reaction can be carried out perfectly.

Other processes that the author mentions, but does not specially criticise, are those of Beilby (this Journal, 1882, 744), and of Grouven (Ger. Pat. 3881, 1878), who uses peat or Greenland moss, and of Harrez (Dingler's Polyt. J. 195, 535), in which an intimate contact between the potash, carbon, and ammonia is obtained by calcining suit with charcoal.

II. Production of Potassium Cyanide by means of Atmospheric Nitrogen.—The formation of potassium cyanide by the intervention of the atmospheric nitrogen was first noticed in the blast furnace. In 1835, Dawes pointed out the presence of this substance, and its formation from the atmospheric nitrogen was fully proved by Bansen and Playfair (Report of the B. Assoc. 1845, p. 185). Lewis Thomson; 1839, made the first real attempt to prepare cyanogen compounds from atmospheric nitrogen. The first patent was taken out by Newton in England in 1843, and Possoz and Boissière were the first who carried out the process on a commercial scale. At their works at Grenelle, near Paris, in 1843, they manufactured 15,000 kilos. of yellow prussiate of potash; but in 1844 they removed to Newcastle-upon-Tyne, where they made 1,000 kilos. of yellow prussiate daily at the cost of 2 francs per kilo. In 1855, their works were closed on account of insufficient demand and the too high cost of production. By their process, a stream of air was passed over charcoal impregnated with 30 per cent. of potash, and heated to a white heat. The apparatus was in the form of a cylinder, and was continuous, being fed at the top, whilst the charcoal, charged with potassium cyanide, was taken away at the bottom. On the removal of the works to Newcastle, an improvement in the apparatus by Bramwell was adopted, by which the fire gases which heated the cylinder were led through the cylinder itself, so that the same volume of air served both for heating and for making cyanogen. Many modifications of the process have been devised. Armengaud in 1846 took out a patent in France for making yellow prussiate from atmospheric nitrogen, which differed from others in that he mixed water vapour with the air. Margueritte and De Soudreval found that baryta transformed the nitrogen of the air into cyanogen compounds much more readily than potash and soda. They ascribed this to the fact that it was porous, and did not melt, and that it was also less volatile. Their process was abandoned because it could not compete with the ordinary fusion process for making yellow prussiate.

Weldon, in 1878, observed that the formation of cyanide by the action of nitrogen upon alkali and carbon proceeded more rapidly at lower temperatures than it had been customary to use. He found the best heat to be one of bright redness, and not of whiteness.

Von Adler found that the alkalis and alkaline earths were readily converted into cyanogen compounds when a mixture of the former with carbon was heated in an atmosphere of nitrogen to which hydrocarbons or carbon monoxide had been added; and, further, that the action was assisted by the presence of iron, manganese, nickel, or other metal which had a tendency to combine with carbon.

Readman likewise uses alkaline earths and carbon, which he heats in an electrical furnace in a stream of nitrogen.

Mond, in 1882, took out a patent for a mixture of carbon, barium carbonate, and magnesia, which he formed into blocks, and heated at a high temperature in the presence of nitrogen.

All the methods described depend upon the same principle, viz., the action of nitrogen upon a heated mixture of alkali and carbon. Nevertheless the reactions are not yet fully understood. It was, and is still, generally held that they are the same as those Liebig propounded for the ordinary yellow prussiate process, according to which the nitrogen combines with the carbon to form cyanogen, which in its turn combines with the base to form a cyanide. Apart

from the objection that in the ordinary prussiate process the nitrogen is not free and therein differs from this process, there is the further objection that carbon and nitrogen in the free state do not combine even at the highest temperatures. Morren, however, states that they combine when an induction spark passes between carbon points in an atmosphere of nitrogen, and that a direct combination at a bright red heat only takes place under great pressure. A consideration of the thermo-chemical data for the formation of KCN from its elements shows that the heat of formation amounts to +32,500 cals., whilst the formation of KCN from K and CN produces +65,350 cals. (Thomson), and that H + CN produces 7,800 cals. It, therefore, is possible for C and N to combine directly to form cyanogen in the presence of potassium, it follows that their combination will take place with much greater difficulty in the presence of the more difficultly reducible sodium and barium bases, and, further, that the presence of water vapour can only serve to make the reaction slower. Possioz has, as a matter of fact, shown that when soda is used, the formation of cyanogen is more difficult to effect than when potash is used; but, on the other hand, Marguerite, Mond, and others have proved, that with baryta it proceeds much more readily than with soda; and Armstrong has further shown that the presence of water vapour is in no way injurious; and these facts are in direct contradiction of the assumed theory of the direct combination of carbon and nitrogen.

The experience gained in carrying out these various processes also indicates that the formation of potassium cyanide is not due to the combination of potassium with cyanogen; for if this were the case, an elevation of the temperature would be favourable to the process, whereas Weldon and others have shown that the opposite is the case. Further, a prolonged contact of nitrogen with the carbon would be desirable in order to produce cyanogen, but experience has shown that the length of time of contact between the nitrogen and the carbon is of little consequence, but that an intimate mixture of the materials is of great importance. This last consideration also excludes the hypothesis that the formation of cyanogen is dependent upon the formation of a nitride of the alkali used, for then the success of the reaction would be influenced by the time of action of the nitrogen upon the mixture.

The author then argues in favour of the formation of cyanide being due to the production of an alkaline carbide, a view which would explain the more energetic action of barium than that of potassium and sodium, which, owing to their greater volatility, are more readily withdrawn from the sphere of action of the carbon, and therefore form carbides with much greater difficulty than do calcium, barium, and strontium. The theory of the formation of carbides in the cyanide process was put forward by Berthelot in 1869. He showed that acetylene combined with nitrogen to form hydrocyanic acid under the action of the silent electrical discharge, from which he inferred that in a mixture of carbon and potassium carbonate K_2CO_3 was formed, which then absorbed nitrogen and produced potassium cyanide.

The theory of a carbide formation also satisfactorily explains De Lambilly's process (this Journal, 1892, 604 and 1006), which consists in heating a mixture of the carbonates of potassium, barium, or sodium with carbon and lime in a cylinder until CO ceases to be evolved, and then a mixture of equal parts of nitrogen and illuminating gas, poor in hydrogen (or a mixture of 10 parts of carburetted illuminating gas, 2—3 parts of nitrogen, and 1 part of ammonia), is led through the cylinder under a pressure corresponding to from 10—15 c.e. of mercury, the temperature being raised nearly, but not quite, to a white heat. It is also an advantage to add about 50 parts of iron filings to every 100 parts of alkali used. The gases which are evolved consist chiefly of hydrogen. For the new process by J. Young, see this Journal, 1894, 1196.

III. Wet Methods of making Cyanides.—The synthetic methods of making cyanides from ammonia or atmospheric nitrogen have as yet not proved commercially successful; but some success is to be recorded in wet methods of making cyanides.

Wurtz found that methylamine was decomposed at a red heat into ammonia, hydrocyanic acid and hydrogen; Wilm,

Ortleib, and Müller found that trimethylamine was decomposed at a red heat into ammonium cyanide, hydrocyanic acid, and hydrocarbons, and these facts have been carried into practical working at the factory of the Croix Company, who manufacture cyanides from commercial trimethylamine obtained from beet-root molasses.

Of greater importance is the formation of cyanides by the desulphurisation of sulphocyanates. Zeise first pointed out that ammonium sulphocyanate was formed by heating carbon bisulphide and ammonia in alcoholic solution—

and Gélis patented a process founded upon this reaction, which obtained the prize medal at the international exhibition in London in 1862. In Gélis's process, carbon bisulphide is mixed in the cold with ammonium sulphhydrate, whereby sulphocarbonate is formed (poor yield). It is then converted into potassium sulphocyanate. The process failed practically, partly owing to the difficulty of desulphurising the potassium sulphocyanate (the difficulty which is common to all methods of making cyanides from sulphocyanates), but also to the poor yield. The reaction between ammonium sulphhydrate and carbon bisulphide is expressed as follows:— $CS_2 + NH_4.HS = CS.NH_3.SH + H_2S$, that is to say, free dithiocarbamic acid and sulphuretted hydrogen are formed. The free dithiocarbamic acid is, however, readily resolved again into ammonia and carbon bisulphide—

and only so much is obtained as combines with the excess of ammonia present to form the ammonium salt, which is not so readily decomposable.

The process of Tscherniak and Günzburg, which is now being worked in Hamburg by Gröhlich and Wichmann, obviates this last drawback in the Gélis process by the use of ammonia instead of ammonium sulphhydrate—

The ammonium sulphocyanate is then converted into calcium sulphocyanate, and this, by treatment with potassium sulphate, into potassium sulphocyanate, which is then desulphurised by iron.

With regard to the question of desulphurisation of the sulphocyanates, which in the old smelting process for making yellow prussiate was also a weak point, the loss is due partly to oxidation, partly to incomplete desulphurisation. The first source of loss can be overcome by the addition of carbon when fusing with iron; the second source has only lately been overcome. It has been found by Nöllner that by a proper method of lixiviating the fused mass under rigorous analytical control, very good results can be obtained with iron. Sternberg has further found that a very satisfactory desulphurisation with iron takes place when double the theoretical amount of iron in the form of iron filings is heated with the sulphocyanate to 110°—120° under pressure, 80 per cent. of the theoretical yield of yellow prussiate being obtained.

These processes would probably have come into practical use if Playfair (this Journal, 1892, 14) had not discovered that an almost perfect desulphurisation was obtained by the use of zinc or lead instead of iron. Playfair proposes to make sodium sulphocyanate instead of the potassium salt. This is then desulphurised in graphite vessels by smelting with zinc and powdered carbon.

The author draws the conclusion that the processes reviewed under sections 1 and 2 of this paper can only prove successful when the reactions involved are fully understood and the necessary conditions required have been ascertained, and that the use of ammonia has more promise of success than the use of the more inert nitrogen. Further, that the process of Tscherniak and Günzburg deserves full recognition, and that, combined with a good desulphurising method, such as Playfair's, together with cheap ammonia, it will probably be able to compete with the old yellow prussiate process.—H. S. P.

Calcium Chloride from the Ammonia-Soda Process, Utilisation of. H. Schreib. Chem. Zeit. 1895, 19, 1181—1182.

THE author suggests that crystallised calcium chloride might be produced from the end-liquors of the ammonia-soda process, and used as a refrigerating agent. Current prices are prohibitory for this purpose, but the calculated cost of production is not excessive; thus:—Under normal working conditions the end-liquors contain per cubic metre 60 kilos. of sodium chloride and 60 kilos. of CaCl_2 , i.e., 120 kilos. $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$. To evaporate the remaining 900 kilos. of water, there will be needed 130 kilos. of coal, taking the average evaporative duty as 7 kilos. of water per kilo. of coal. Allowing for loss, an output of 110 kilos. of $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ and 55 kilos. of NaCl may be expected. The items of cost are:—Coal for evaporation, 130 kilos. at M. 1.20 = M. 1.56; coal for power, 10 kilos. at M. 1.20 = M. 0.12; labour, M. 0.20; repairs, M. 0.15; interest and depreciation, M. 0.20; the whole amounting to M. 2.23. Allowing the lowest price for the common salt recovered, 100 kilos. of $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ would not cost more than M. 2, and this amount could be reduced by the use of multiple-effect apparatus for concentration.

Having regard to the fact that 1 kilo. of ice in melting absorbs 80 cals., and that 1 kilo. of crystallised calcium chloride in dissolving in water absorbs only 23 cals., it is evident that the latter, to compete with ice on an equal footing, must not cost more than M. 0.5—0.6. But for many purposes calcium chloride would be preferable to ice, even though dearer, because it can be transported in well-closed vessels without loss of efficiency, even under such conditions of temperature as would make the carriage of ice difficult and costly. Moreover, the reduction of temperature which can be attained by the use of calcium chloride is greater than that which can be reached by ice alone, which is necessarily fixed at 0°C . The freedom of calcium chloride from micro-organisms is also an advantage. —B. B.

Calcium Chloride from the Ammonia-Soda Process, Utilisation of. N. Caro. Chem. Zeit. 1895, 19, 1233. (See preceding abstract.)

It having been suggested that the end-liquors from the ammonia-soda process might be used to produce crystallised calcium chloride capable of employment as a refrigerating agent, the author points out that the alleged freedom of calcium chloride from micro-organisms (one of the advantages claimed), is of no significance, because it would in any case only be used in closed circulatory apparatus, and would not replace ice, which is added directly to the material to be cooled. He further considers that the cost of concentration could be lowered by systematic evaporation, as in a spray-column apparatus.—B. B.

The Decomposition of Common Salt in the Production of Sulphate of Soda, or for Analogous Purposes, Improvements in Apparatus for Use in. W. Thomson and P. J. Worsley, Bristol. Eng. Pat. 21,945, Nov. 13, 1894.

IN the improved apparatus described, there is a combination of a pot or pots (into which part of the salt is charged) with a furnace or roaster (into which the remainder of the salt is charged). Thus, in the manufacture of sulphate of soda, a uniform stream of dry or nearly dry hydrochloric acid gas is obtained from the pot, and the same from the

furnace. In the claim there is specially set forth "the combination of a furnace or roaster, and a pot or pots, such as described in detail and illustrated." Both pot or pots and furnace are provided with mechanical stirring gear. —E. S.

Utilisation of Waste or Spent Acid Pickle from Galvanising Works or other Works where Iron is Treated by Acid, and in the Treatment (for the Recovery or Obtainment of Chlorine) of other Products containing Chlorine, Improvements in. T. Parker, Tettenhall, near Wolverhampton. Eng. Pat. 24,859, Dec. 21, 1894.

THE free acid in hydrochloric acid spent pickle is neutralised by digestion with scrap-iron, and the resulting solution of ferrous chloride is evaporated to dryness in a covered vessel. The dry ferrous chloride is heated in a current of air to obtain chlorine and ferric oxide. When the pickling is effected by sulphuric acid, the spent pickle (ferrous sulphate solution) is treated with calcium, magnesium, or sodium chloride, and the corresponding sulphate formed is separated, if calcium sulphate, by filtration, or if magnesium or sodium sulphate, by crystallisation. The ferrous chloride solution is then treated as before described. Chlorine may also be obtained from waste calcium chloride, such as that occurring in the soda manufacture by the ammonia process, by treating it with ferrous sulphate to obtain ferrous chloride, which is applied as before. Similarly, chlorine may be obtained from sodium chloride or magnesium chloride. The ferrous sulphate needed may be obtained by roasting iron pyrites.—E. S.

The Separation of Salts from their Solutions, Process and Apparatus for. C. Kellner, Halluin, Austria. Eng. Pat. 25,368, Dec. 31, 1894.

ADVANTAGE is taken of the diminishing solubilities of certain salts with increasing temperatures to separate such salts from others of which the solubility increases as the temperature rises. Sodium carbonate, for instance, is more soluble in water at 36° than at 100° , whereas sodium chloride increases slightly in solubility within the same range of temperature. Hence, if a hot solution containing caustic soda and common salt be carbonated and further heated, evaporation going on meanwhile, the sodium carbonate separates, when suitable proportions of the two salts are present, as in the cathode liquid obtained in the electrolysis of common salt.

The apparatus for carrying out this process consists of a crystallising tower A, with a vessel B at the top, receiving the solution to be treated, with ropes or chains $s^1 s^2 s^3$ hanging freely from perforations in its bottom, on which ropes the crystals form. The inlet pipe R admits fire gases

from a furnace, which supply the necessary carbonic acid gas, and by their heat, effect concentration of the liquid. The crystals as they fall are withdrawn through the side opening C, whilst the mother-liquor flows through the outlet pipe A, into the receptacle D, whence it may be returned for re-treatment if necessary. The inflowing gases escape by the outlet a^1 .—E. S.

Pure Concentrated Nitric Acid from Dilute or Impure Solutions, Improvements in Obtaining. Dr. F. Valentiner, Leipzig, Germany. Eng. Pat. 19,192, Oct. 12, 1895.

This process consists in redistilling dilute or impure nitric acid, first mixed with concentrated sulphuric acid, in vessels partially or entirely deprived of air. Apparatus applicable for the process is described in Ger. Pat. 63,207.—E. S.

VIII.—GLASS, POTTERY, ENAMELS.

Ceramic Clays of the United States. K. Langenbeck, Thonind. Zeit. 1895, 19, 242.

CERTAIN so-called "flint-clays" occur in hard, rock-like masses, which absorb water greedily without noteworthy rise of temperature, and disintegrate, but without becoming workable even after a year's weathering. When ground with water, however, these clays yield a good plastic product. A typical composition is: True clay, 82.85 per cent.; quartz, 16.58 per cent.; felspar, 1.35 per cent. Suitable glazes are of the formulae: 11PbO ; $0.2\text{Al}_2\text{O}_3$; 2SiO_2 ; and 0.8PbO ; 0.1CaO ; $0.1\text{K}_2\text{O}$; $0.2\text{Al}_2\text{O}_3$; 2SiO_2 .—B. B.

Gray Under-Glaze. Sprechsaal, 1895, 28, 526.

A mixture of 772 parts oxide of tin, 76 parts felspar, 76 parts of crystallised borax, 76 parts of antimonium diaphoreticum (potassium antimonate), well powdered, mixed, and calcined in an earthenware kiln, is said to have resisted well the higher glazing temperatures, and not to have turned blue.—A. C. W.

Cements, Improvements in and relating to the Manufacture of, for Making Mortars suitable for the Production of Artificial Stone. E. Weekwarth, Lima, Peru, and Max Hoett, Berlin. Eng. Pat. 21,731, Nov. 10, 1894.

HIITHERTO albuminous cements have been made with the albuminous material in its natural wet or adhesive state, a condition which has rendered it difficult to obtain uniform mixture. In the present process, the albuminous material is dried and brought to a floury consistency. The substances may be mixed in aqueous or alkaline solution. Besides albumin: potash, lime, potash alum, borax, and plaster of Paris are used.—V. C.

Sifting Cement, Improvements in Apparatus for. C. H. Watson, W. Bartholomew, W. Holden, Greenhithe. Eng. Pat. 25,152, Dec. 27, 1894.

CEMENT falls from the stones on to a horizontal sieve, to which is given a reciprocating motion by a connecting-rod and eccentric. The suspension of the sieve is arranged so as to traverse the material sifted from one end to the other. Loosely-suspended rods, against which the sieve strikes in its travel, afford a vibratory effect.—B. B.

Blast-Furnace Slag and other Slag, Improvements in the Manipulation and Treatment of, and in Apparatus therefor. T. Hydes, London. Eng. Pat. 465, Jan. 8, 1895.

THE economic application of blast-furnace slag has hitherto been hindered by the cost of disintegrating the large blocks in which it is customarily allowed to form. In the present invention the molten slag is caused to run in small streams down inclined surfaces, whereby it breaks up into globules. By the rapid chilling of these globules, the resulting material becomes very brittle, so that it can be readily pulverised (as is required in the manufacture of cement); and, on the other hand, by allowing the globules to cool gradually, a very tough material may be obtained which is suitable for making roads.—V. C.

X.—METALLURGY.

Improved Ten-Ton Chlorination Barrel. Eng. and Mining J. 60, 1895, 370.

THE apparatus, which is lined with lead, was devised for use in the chlorination of gold ores, but it is suitable for use in other cases where ores have to be agitated with acid solvents. Where cyanide is to be used as a solvent, the joints of the shell should be well caulked and the lining omitted. The barrel, which revolves horizontally, is 15 ft. in length, by 5 ft. 2 in. in diameter. The heads are flanged spherical segments $\frac{1}{2}$ in. thick. To the shell are fastened manholes or charging-hole castings and the carrying flanges that support the tires on which the whole revolves. All joints of the shell are butt-jointed, with cover-plate, and are double-riveted; all rivets and bolts have countersunk heads on the inside, to leave a smooth surface.

The tires are heavy cast-iron rings, bolted to the carrying flange. Two manholes are provided for charging and discharging pulp. The shell is calculated to stand a working pressure of 60 lb. per sq. in.

The lead lining, when the harrel is used for chlorination, is of 18-lb. chemical sheet lead. It is put in, carefully dressed back against the shell, and bolted in place with a large number of flat-headed bolts. Flanges tapped for 2-in. pipe are fastened with tap bolts to the shell at top and bottom, for the inlet and outlet of wash water and solution; also holes are bored for the inside filter frame.

The tires revolve in a set of trucks carrying four rollers, two of which serve as the friction-driving rolls, and are keyed to a shaft, to which is also keyed the large spur-driving gear; the other two rollers are keyed to gudgeons, and revolve free. The speed of the revolving cylinder is about $8\frac{1}{2}$ revolutions per minute.

The total weight of the machine, as estimated, is about 28,000 lb.; the weight of the heaviest piece, the cylinder with lead lining, being about 14,000 lb.; without the lining, about 9,100 lb. The harrel is fitted with a sand-filter of the kind described in the Eng. and Mining J. for September 21st, 1895, 273.—J. H. C.

Cyanide Process for Gold Treatment, Contributions to Chemistry of. E. A. Schneider. Eng. and Mining J. 1895, 489, 514.

To determine the absolute effect of oxygen on cyanide solutions, a series of small-scale experiments was tried, from which it was found that oxygen oxidises cyanide to cyanate, but less energetically than is frequently assumed, and more readily in dilute than in strong solutions; which accords with Maclaurin's observation that the weaker solutions absorb the larger volume of oxygen. But the loss of cyanide observed with 50 c.c. of a 0.25 per cent. solution of KCy, kept in contact with 250 c.c. of oxygen for a week in a closed bottle, and exposed to sunlight, was only 2.78 per cent.; whilst a similar solution left for a week in the dark lost only 1.13 per cent. Stronger solutions lost less in the sunlight, and were unchanged in the dark. The presence of cyanate was determined by a reaction described in a separate abstract (page 51).

Experiments with carbon dioxide showed that when cyanide solutions of varying strengths were exposed in shallow dishes to the air, the weaker solutions suffered relatively most, but absolutely least, alteration; but when a constant weight of potassium cyanide was dissolved in varying volumes of water, the most dilute solution was least affected, both absolutely and relatively, by the carbon dioxide of the air. The range of decomposition was from 28 to 66 per cent. in one day. But solutions of uniform strength, exposed so that the depth of column varied, lost practically the same amount, per unit of time, in all cases, showing that the layer of solution affected by the carbonic acid is of practically constant depth. Agitation of the solution is equivalent to increasing the depth of the layer. A covering film of coal-oil, estimated at 0.04 mm. in thickness, was observed practically to prevent the decomposition of the cyanide. By treating cyanide solutions with a large excess of pure carbon dioxide in closed bottles, and examining the residue, it was found that either of two equations might be correct:—

The resulting mixture of potassium carbonate or bicarbonate with hydrocyanic acid was found to be an excellent solvent for gold, provided that oxygen was present.—W. G. M.

Composition for Polishing Metal. W. A. Rayner, Kimberley, Cape of Good Hope. Eng. Pat. 17,321, Sept. 17, 1895.

"An ounce of aqueous ammonia" is diluted with 3 oz. of water, coloured with 3 grains of orange dye, and made up to 6 oz. by the addition of prepared chalk. The product is rubbed on the metal to be polished, until dry.—B. B.

Alloys, Improvements in, for Anti-Friction Purposes. M. Wagner, London. Eng. Pat. 22,199, Nov. 16, 1894.

ACCORDING TO THIS improvement, the alloy is prepared of lead, tin, and antimony, with the addition of a small quantity of either barium, cesium, calcium, cerium, didymium, lanthanum, potassium, rubidium, strontium, tellurium, thorium, zirconium, or an admixture of any of them. All the metals are fused separately, and the molten lead well washed with sal-ammoniac, after which the molten tin is poured into the cleansed lead; then the antimony is added and well stirred. A small quantity of one or more of the above-mentioned metals is then added, the proportion varying according to the nature of the work required of the bearings. The alloy is usually composed as follows:—80 lb. lead, 15 lb. antimony, 5 lb. tin, and for light-running shafts, from 0.25 to 0.50 per cent. of either of the other metals; or for heavy-running shafts, 0.5 to 1 per cent. The compound is poured into moulds, and when cold and set, the working surface is dressed ready for fitting.—G. H. R.

Producing Magnetic Oxide on Wrought or Cast Iron, An Improved Method of. P. H. Bertrand, Paris. Eng. Pat. 23,855, Dec. 7, 1891.

See under XIII. B., page 40.

Gold Solvents, Improvements in the Manufacture of. J. J. Hood, London. Eng. Pat. 882, Jan. 14, 1895.

A CRUDE alkali cyanide is freed from sulphides by any known process, as by agitation of the solution with white lead or litharge; and a mercury compound, "such as the chloride," is added, and the mixture is evaporated to dryness; or it is concentrated until a double salt crystallises out. Varying proportions of the constituents may be used, as two parts of mercury chloride to one of potassium cyanide, or equal weights of each. Caustic alkali may be added, in which case suitable proportions are: mercury chloride, 5 parts; alkali cyanide, 10 parts, and caustic alkali, 1 part. Instead of mercury chloride, a lead compound may be taken, obtained by boiling litharge with caustic soda solution, to which the inventor adds "varying quantities of potassium or sodium cyanide, or mixtures of these," and evaporates to dryness. It is claimed that the preparation of these solvents avoids the losses contingent on the evaporation of a simple alkali cyanide solution.—E. S.

The Utilisation of Liquors from Chlorination-roasted Ores or Tailings, Improvements relating to. H. Brewer, Duisburg, Germany. Eng. Pat. 1348, Jan. 19, 1895.

THE liquor obtained by lixiviating "chlorination-roasted" zinc ores, with or without pyrites or iron oxides, and containing sodium sulphate and chloride, zinc chloride, iron sulphate, and salts of manganese, cobalt, nickel, and silver, is treated with calcium chloride, preferably that occurring as a by-product in the ammonia-soda process, and the calcium sulphate precipitated, is separated. After precipitation of any silver present, the ferrous salt is oxidised by air, and thrown down as ferric hydroxide by calcium carbonate. Cobalt, manganese, and nickel are precipitated by chlorine or bleaching-powder, and the liquor, now containing substantially zinc, sodium, and calcium chlorides, is evaporated; the sodium chloride that salts out is removed for application in the chlorination process, and the mother-liquor is electrolysed to obtain zinc and chlorine.

When the chlorination-roasted ores are cupreous, the silver and copper may be separated from the liquor either before or after the treatment with calcium chloride. The copper can be separated by iron or by electricity with simultaneous elimination of chlorine, or by both processes.

—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Carbon, Transformation into Plumbago. J. Reyval. L'Éclairage Électrique, 1895, 4, 451; Proc. Inst. Civil Eng. 1895, 123, 78.

Messrs. Girard and Street have devised several special kinds of electric furnaces for the purpose of transforming carbon into graphite. The author thus describes these furnaces and the process:—The carbon rod to be converted into graphite is passed through a block of refractory material, having a small heating chamber in the centre.

A second carbon enters this chamber at right angles to the first carbon, and an arc is maintained between the two. The speed at which the first carbon is caused to pass through the chamber is regulated in accordance with the temperature to which it is to be raised. In the case of circular carbons for arc-lighting, the carbon rod to be converted is given a motion of rotation as well as of translation. The effect is then as follows:—The action of the arc leaves a spiral trace on the carbon to be converted. Its size on a 0.55-in. diameter carbon with a 40-ampere arc, was $\frac{1}{16}$ in. broad and about $\frac{1}{16}$ in. in depth, and this represents the carbon converted into graphite.

By regulating the speed with the temperature the whole surface of the carbon can easily be converted. In this process the carbon to be treated was connected to the positive pole. The alterations effected were as follows:—The electrical conductivity of the carbons is increased in the ratio of 1 to 4, and the conductivity to heat in about the same proportion. The density of the untreated carbon of 0.55 in. diameter was 1.98, and after treatment was increased to 2.6. The proportion of carbon converted into plumbago was in this case 85 per cent. of the whole. The carbon so treated is being used in arc-lamps, for the brushes of dynamos, and as electrodes in the electrolysis of alkaline salts.

Gas Batteries, Improvements in. H. T. Barnett, London. Eng. Pat. 23,590, Dec. 3, 1894.

The inventor proposes the use of a carbon electrode of numerous short outstanding filaments in contact with a suitable conducting support. Carbonised velvety fabrics are claimed. The object is to increase the occlusive power for the gas in which such an electrode is employed.

—J. C. R.

Primary Batteries, Improvements in. E. M. Levetas, H. Levetas, and W. Rowbotham, Birmingham, England. Eng. Pat. 107, Jan. 2, 1895.

The object of this invention is to utilise the increase of temperature which takes place in the working of a cell, to provide for the circulation of the electrolyte in order to diminish polarisation, and relates to that class of battery in which carbon is the positive, whilst iron or other suitable metal is the negative element. The cell is divided into four or more compartments by the plates, which are placed near to one another, and are provided with circulation openings at the top and bottom, so that the heated fluid between the carbon and the metal plates can rise and flow into the outer compartments.—G. H. R.

Oxygen into Ozone, Apparatus for Transforming. M. Otto, Paris, France. Eng. Pat. 748, Jan. 11, 1895.

The apparatus consists of a rectangular box of wood coated internally with a protective varnish, and standing on insulating feet. The box contains a series of parallel elements, each consisting of two glass plates having perforations at their one end, and having between them a sheet of aluminium or other conducting material, stopping short of the perforations, which are arranged alternately at the lower end of one element and at the upper end of the next one. The end plates are only provided with one opening for the entry and egress respectively of the gas to be ozonised. The glass plates are separated by thin strips of asbestos, and the end plates rise above the others, the trough-like space thus formed being filled in with suitable cement to seal the box hermetically. The alternate conducting plates are connected to one terminal, whilst the remaining plates are connected to the other pole of a Ruhmkorff coil or high-tension alternating current generator. The electrical discharge takes place across the spaces between the successive elements, whilst the current of oxygen to be ozonised flows in a zigzag course through the apparatus.—G. H. R.

Electrical Storage Batteries, Improvements in. J. B. Marchant and J. Woolley, London. Eng. Pat. 1676, Jan. 24, 1895.

These improvements relate to the construction of electrodes for secondary batteries of lead shot, solid or hollow, retained in either metallic or non-metallic, perforated or non-perforated vessels.—J. C. R.

Electric Accumulators, Improvements in and relating to. O. Pirsch, Liège, Belgium. Eng. Pat. 1717, Jan. 24, 1895.

The plates are constructed of a thin metal plate surrounded by a frame of similar metal, the core of which is provided with projections, protuberances, or rents in the metal, which are so arranged that their curved outer extremities hold the active material in contact with the metallic core. The plate is filled up to the depth of the frame with active material, which is loosely compressed, and is maintained against the core by the claw-like protuberances. It is claimed that this construction allows the electrolyte to penetrate throughout the mass, and renders the whole active, whilst the numerous protuberances ensure good conductivity.—G. H. R.

Primary Batteries, Improvements in and relating to. W. Rowbotham and H. S. I. Levetas, Birmingham. Eng. Pat. 7600, April 16, 1895.

This relates to single-fluid primary batteries, and has for its object the circulation of the exciting fluid for reducing polarisation. This is effected in a battery of cells by suitable openings for the flow of the electrolyte, arranged alternately at top and bottom of the dividing walls. Where iron and carbon form the couple, the following is given as the electrolyte:—Bichromate of soda, 1 part; sulphuric acid, 5 parts; water, 25 parts. Eng. Pat. 107 of 1895 is referred to (see Col. 1).—J. C. R.

Primary Batteries, Improvements in and relating to. W. Rowbotham and H. Levetas, Birmingham. Eng. Pat. 13,730, July 18, 1895.

The essential features of these improvements are in the direction of circulation of the electrolyte and the construction of the carbon elements in the form of tubes having their upper ends open to the atmosphere.

An iron electrode is enclosed in a bag or covering of flannel. The battery solutions consist of bichromate of soda and dilute sulphuric acid for the carbon elements, and sulphuric acid and water for the iron elements.—J. C. R.

Galvanic Batteries, Improvements in. R. W. Gordon, Massachusetts, America. Eng. Pat. 13,900, July 20, 1895.

In the improved cell the positive element is formed of zinc, which is preferably fluted, while the negative element is copper or iron, and the depolarising agent black oxide

of copper, the exciting fluid being a solution of caustic soda. The elements are contained in a jar provided with a tightly-fitting cover which has a central opening closed by a plug of insulating material, from which the zinc is suspended. The negative element is arranged concentrically around this, and is suspended from the cover. It consists of a receptacle formed of concentric perforated inner and outer walls, closed at the bottom by an annular plate, the space between the walls being filled with black oxide of copper.—G. H. R.

Primary Batteries, Improvements in and relating to. W. Rowbotham, Birmingham. Eng. Pat. 14,158, July 25, 1895.

THE claim here is for a primary cell in which the carbon elements consist of porous carbon tubes which are open to the atmosphere at both ends (see foregoing abstract of Eng. Pat. 13,739, above).—J. C. R.

Primary Batteries, Improvements in and connected with. W. Rowbotham, Birmingham. Eng. Pat. 15,371, Aug. 15, 1895.

A PRIMARY cell is claimed in which the carbon elements consist of plates of porous carbon or graphite having passages extending through them from edge to edge and open to the atmosphere (see page 39).—J. C. R.

Galvanic Dry Cells, Improvements in. C. E. C. Jungnickel, Altona, Germany. Eng. Pat. 17,259, Sept. 16, 1895.

TO avoid the bursting of the seal, or closure of the cell, or even the cell itself, by interior evolution of gas, in the case of dry cells, the inventor applies a gas regulator in the shape of an inverted closed tube or chamber of glass placed in the cells. At the bottom of this "regulator" is a small aperture. If gases are generated inside the cell and not able to escape with sufficient rapidity, they will force the electrolyte through this small aperture into the regulator, the air in which will be more or less compressed and so act as a regulator.—J. C. R.

Electric Batteries, Primary, Improvements in. M. M. Bair, Paris, France. Eng. Pat. 17,603, Sept. 20, 1895.

THE claim is for an electric battery, the negative electrode of which has "agglomerate" (peroxide of manganese and carbon) blocks, or pieces, secured thereto by screw bolts, studs, or pins.—J. C. R.

Galvanic Batteries, Improvements in Tubular. E. S. Boynton, Brooklyn, U.S.A. Eng. Pat. 20,214, Oct. 26, 1895.

THIS invention relates to galvanic batteries in which all the cells or elements are merged or combined into the form of a common receptacle for the liquid electrolyte. One of the electrodes (carbon) forms a fixed part of said receptacle (shown as a cylinder), and the other (zinc) being removable.—J. C. R.

(B).—ELECTRO-METALLURGY.

The Nickel-plating of Wood, Processes for. Dingler's Polyt. J. 298, [3], 72.

THE articles to be nickel-plated must first of all be coated with metal; for this purpose the following three solutions are employed:—I. $1\frac{1}{2}$ grms. of caoutchouc slices are dissolved in 10 grms. of carbon bisulphide, and 4 grms. of melted wax are poured into the solution. A mixture which has been prepared beforehand, consisting of 5 grms. of phosphorus in 60 grms. carbon bisulphide, with 5 grms. turpentine and 4 grms. of powdered asphalt, is then added, and the whole shaken. II. 2 grms. of silver nitrate are dissolved in 600 grms. of water. III. 10 grms. of chloride of gold are dissolved in 600 grms. of water. The conducting wires are attached to the article, which, after being immersed in the first solution, is allowed to dry. The second solution is poured over it, and it is kept suspended until the surface has a dark lustre, when it is rinsed with water and treated

in a similar manner with the third solution. The surface has now a yellowish sheen, and the wood is sufficiently prepared for electrolytic deposition.

Langbein's dry process consists in quickly pouring over the article a colloidal solution of potassium iodide, diluted with an equal volume of ether-alcohol; when the layer is just about to set, the wood is laid in a weak solution of silver nitrate, light being excluded. As soon as a yellow colour appears, the wood is rinsed, exposed to sunlight, and covered with copper, prior to being nickel-plated.

Wooden handles for surgical instruments may be treated by immersion in an ethereal solution of paraffin or wax, and when the ether has evaporated, fine graphite is powdered over them, or the wax is covered with bronze powder, and all unevenness of surface removed. When the articles are to be electrolytically coated with copper, they are placed in a bath, the composition of which varies with the current employed; generally, it consists of 30 litres of 18 per cent. copper sulphate solution, and $1\frac{1}{2}$ litres of 66 per cent. sulphuric acid. When a sufficient amount of copper is deposited, the articles are ground, polished, and nickel-plated in a bath composed of 500 grms. of ammonium nickelous sulphate, 50 grms. of ammonium sulphate, and 10 litres of distilled water. If blue litmus paper be quickly reddened by this solution, the acidity is reduced to such a point by addition of ammonium chloride, that the reddening is only slowly developed.—J. L. B.

PATENTS.

Metallic Alloys, Process for the Treatment of certain, for the Manufacture of Elements for Voltaic Batteries and Caustic Alkalis or their Derivatives. L. P. Halin, Modane, France. Eng. Pat. 23,198, Nov. 29, 1894.

ACCORDING to this process, the alloys employed are those described in Eng. Pat. 23,117, Nov. 28, 1894 (this Journal, 1895, 1049), and it is preferred to construct the electrodes by casting an alloy of barium and lead round a lead grid, but a support of any metal less fusible than the alloy, such as copper, may be used; and the alkali metal forming the alloy depends on the nature of the alkali to be produced. The castings are arranged in a series of troughs alternately, between carbon plates of the same sign, and the spongy plates are arranged in a second series, all the plates of like sign being connected together in each series. The metal plates of the first series are then connected to the carbon plates of the second, whilst, correspondingly, the spongy plates of the second series are connected to the carbon plates of the first. The first series of troughs, which contain the plates of alloy, are filled with a cold solution of alkaline nitrate, sulphurous acid, or sulphites, according to the by-products required; whilst the second series of troughs, in which the plates are to be peroxidised, are filled with a dilute solution of sulphuric acid.—G. H. R.

Zinc and Lead, Process and Apparatus for the Production of, by Electrolysis of the Melted Chlorides. R. O. Lorenz. Eng. Pat. 25,074, Dec. 24, 1894.

THE object of this invention is to effect the working of ores or residues, or alloys containing zinc and lead, by converting them into chlorides and subjecting them to fractional electrolysis at a temperature of from 450° C. to 680° C., with the addition, as may be required, of small quantities of litharge, red lead, peroxide of lead, zinc oxide, or other metallic oxides or peroxides, or of common salt, potassium chloride, magnesium chloride, calcium chloride, sodium fluoride, or similar fluxes for preventing frothing and for regulating the process. The ores or residues are lixiviated by means of hydrochloric acid or acetic acid, with precipitation, if required, of the lead and silver chlorides by the addition of concentrated hydrochloric acid, or introduction of hydrochloric acid gas. The electrolysis is effected in an inclined trough of porcelain or fireclay, which is enclosed in an iron casing, and has an air-tight cover through which the electrodes are passed. Suitable means for charging and for leading off the gas are provided, and at the lower end is a depression or pocket connected with a pipe through which the metal produced during electrolysis can be drawn off. Both the electrodes are made of carbon, and given the form

of a grating, so that the gas generated on the under side of the anode can freely rise, whilst the metal deposited on the cathode can fall through to the bottom of the vessel. The anode is placed about the middle of the vessel, and above the cathode.—G. H. R.

Aluminium, A New Process for the Electrolytic Preparation of. A. Roger, Paris, France. Eng. Pat. 6131, March 28, 1895.

The process consists in the electrolysis of an alkaline solution prepared from bauxite, in an ebullite vat, the bottom of which is covered with a layer of mercury, which forms the cathode. The anode is prepared from finely powdered bauxite and crude petroleum mixed in suitable proportions to form a thick paste, which is rolled into a conical shape, and then calcined at a high temperature in a closed jar. Suitable means are provided for stirring the electrolyte whilst the process is in operation, and for withdrawing the amalgam formed. The aluminium prepared in this way contains 2 per cent. of sodium, which is stated to be an advantage, as it protects the aluminium from oxidation when it is cast into ingots.—G. H. R.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Lard, Analysis of. A. Goske. Chem. Zeit. 1895, 19, 1043.

See under XXIII., page 53.

PATENTS.

Vegetable Fibre Soap. E. Uebrig, Berlin. Eng. Pat. 18,017, Sept. 26, 1895.

In place of the pumice powder often added to soaps in order to increase their detergent properties, the inventor uses sawdust, "wood flour," ground wood, &c.—F. H. L.

Suint from Wool, Improvements relating to the Removal of, Recovering or Separating Certain Constituents from the Suint, and Obtaining Certain Valuable Products therefrom. H. E. Newton, London. From J. H. Wingfield, Montclair, N.J., U.S.A. Eng. Pat. 20,433, Oct. 29, 1895.

The solvent employed in this process for treating the wool, consists of a heavy petroleum oil (sp. gr. 0.837–0.878) at a temperature of 120° F. On cooling the resulting liquid to about 70° F., the cholesterol of the suint separates out as a heavy deposit, while the "glycerides" remain in solution. This solution is found to be an efficient substance for the scouring of the wool, leaving it in a condition suitable for the subsequent carding, &c. The wool is treated with the petroleum oil in an ordinary wool-scouring bowl fitted with pressure rollers. One-half to one gallon of solvent is employed per lb. of wool, and after about 20 minutes' action, the greater part of the liquid is drawn off, the operation being repeated if necessary. The wool is treated with water or neutral soap, rinsed, pressed, and dried. After filtration, the liquid is cooled, the deposit removed, and the clear solution used over again. The latter may also be employed as a lubricant, or for use on leather, and, containing no free fatty acids, it is much better adapted for either purpose than the analogous mixture of dégras and petroleum oil.—F. H. L.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

PATENT.

Drying and Packing White Lead and the like, Improvements relating to. E. J. Read, St. Albans. Eng. Pat. 24,746, Dec. 20, 1894.

The lead is dried in a flat metal pan, heated from below, over which a traveller works on rails. The traveller carries

a number of stirrers extending to the bottom of the pan, and also an ejecting device, which, every time the traveller reaches the end of its stroke and arrives at the edge of the pan, pushes a certain amount of the material into a shoot leading to the casks to be filled. The whole apparatus is covered with a movable hood connected with a chimney.—F. H. L.

(B.)—RESINS, VARNISHES.

PATENTS.

Producing Magnetic Oxide on Wrought or Cast Iron, An Improved Method of. P. H. Bertrand, Paris. Eng. Pat. 23,855, Dec. 7, 1894.

ONE part of manganese peroxide is boiled with 99 parts of "oil" until it is converted into sesquioxide. The resulting varnish is applied to the iron after cleaning, and the articles are heated to 800°–1,000° C. for about 20 minutes. Further decomposition occurs, the manganese being converted into Mn_2O_3 , whilst the iron becomes coated with a film of the similar (magnetic) oxide. The manganese may also be used in the form of a 3 per cent. aqueous solution of the acetate, or the moulds in which the iron is cast may be varnished with the above material.—F. H. L.

Metal Glazing Bars, Enamelling or Varnishing. E. B. and J. H. Podmore, Brighouse, Yorkshire. Eng. Pat. 25,241, Dec. 29, 1894.

THE "glazing bars" of the roofs of greenhouses, &c., are coated with a mixture of anise, poppy-seed oil, carbolic acid, and turpentine.—F. H. L.

Protecting Bright Metals, Improved Varnish for, and Solvent for Removing such Varnish when required. H. Crowther, Leeds. Eng. Pat. 2196, Jan. 31, 1895.

THE varnish consists of dammar dissolved in benzene or similar liquid; and the solvent, of nitrobenzene (1 part) and crude benzene, &c. (3 parts).—F. H. L.

(C.)—INDIA-RUBBER, &c.

African India-Rubber. A. Dewèvre. Ann. Soc. Scient. de Bruxelles, 1895, 19.

THE following are the most important species of *Landolphia* found in Africa from which rubber is obtained:—*L. Petersiana*, *senegalensis*, *lucida*, *ovariensis*, *tomentosa*, *kirkii*, *madagascariensis* (in Madagascar). The widespread *L. comorensis* var. *florida*, however, yields a product of little value, used only to adulterate saps of better quality.—A. C. W.

PATENT.

Plastic Rubber Compounds (Old Rubber Goods), Improvements relating to the Treatment of. H. H. Lake, London. From W. Cable, Boston, U.S.A. Eng. Pat. 1948, Jan. 28, 1895.

IN working up old articles made of rubber, it is usual to pass the material through a roller mill which produces a sheet of about $\frac{1}{16}$ in. in thickness, in order to be able to see and pick out the impurities. According to this patent, the mill is fitted with three rollers arranged vertically over one another, the top pair running at about equal speeds in contrary directions, and being set at the required distance apart. The rubber is made to pass between them, then over the middle roller, where it is inspected, and the foreign matters removed. It then travels to the third roller, geared at half the speed, and set at double the original distance from the middle one. By this construction, the sheet thickens up again, and can be caught by a small delivery roller without fear of tearing it—an accident that frequently happens to the calenders of ordinary construction, involving the stoppage of the machine.—F. H. L.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Disinfection of Hides in the United States. Board of Trade J., Jan. 1896, 62.

A DESPATCH, dated 12th December last, has been received from the Foreign Office, inclosing copy of a circular issued

by the United States Treasury Department, containing the following revised regulations for the disinfection of hides:—

"Representations having been made that the process promulgated on November 14, 1895 (this Journal, 1895, 1052), for the disinfection of hides of neat cattle intended for shipment to the United States, is attended with injury to the hides, the following method, suggested by the Department of Agriculture, is adopted hereby, and will be required in all cases of shipments of such hides, when not dry-salted or arsenic-cured, from the countries of Europe, Asia, Africa, Australia, and South America, viz.:—

"Dry hides which have not been salted or arsenic-cured should be disinfected. Disinfection with sulphur dioxide may be accepted in case a room is provided which can be tightly closed, and also in case the bundles of hides are undone and each hide suspended separately from the ceiling in such a manner that there may be free circulation of the sulphur fumes, and that all parts of the surface may be acted upon. There should be at least 4 lb. of sulphur burned to each 1,000 cubic feet of air space, and the room should be kept closed and the hides subjected to the sulphur dioxide for six hours; or the dry hides may be immersed in a 4 per cent. solution of carbolic acid, or a 1 to 1,000 solution of bichloride of mercury, until they are thoroughly wet with the disinfectant. Fresh or moist hides, whether salted or not, should be disinfected by immersion in a 5 per cent. solution of carbolic acid, or a 1 in 1,000 solution of bichloride of mercury.

"It should be understood that the regulations herein provided do not in any way modify or affect any regulations concerning disinfection issued under the quarantine laws of the United States."

PATENTS.

Marbled Leather, Improvements in the Manufacture of. R. Haddon, London. From J. Scholl, New York, U.S.A. Eng. Pat. 16,493, Sept. 3, 1895.

THE skins are tanned, preferably with sumach, stretched and dried, scraped on the flesh side, and nailed to boards. To effect the marbling, the oil colour (aniline colours are not suitable) is dropped on to the surface of a solution of salt in a vat and caused to form any desired configuration by imparting to the water an appropriate movement, either by fanning it or stirring it, or by dissolving a small quantity of potassium carbonate in the water. If more than one colour is to be used, each is added in turn. The skin, nailed to its board, is now introduced in an inclined direction, so that the surface of the skin takes up the colour or colours floating on the water. The coloured skins are dried in a heated room, removed from the boards, and passed through slightly heated calendering rolls. Excess of colour is removed by a soft brush and the skin again calendered. The dried skin is next polished with a solution of shellac in alcohol, on the coloured surface, and finally rendered pliable by scraping its back with a suitable knife.—A. G. B.

Raw Hides, An Improved Process and Apparatus for the Treatment of. A. F. Diehl, Weimar, Germany. Eng. Pat. 18,178, Sept. 28, 1895.

THE improvement is in the liming process. Instead of being laid away in a pit containing milk of lime and periodically withdrawn for the purpose of plunging the pit, the hides are suspended, by means of hooks, in a vertical position in the pit, and the milk of lime is kept in

rotatory and upward movement by the revolution of a vertical shaft, which carries four radial blades at the bottom of the pit. Two of these blades are set at an angle so as to cause the upward movement of the liquor. It is claimed that the softening of the hair roots is much expedited by this movement, and that the hides benefit from not being exposed to the air. The system may be applied to any unhairing process in which a liquid is used.

—A. G. B.

XV.—MANURES, Etc.

Leather Waste, Agricultural Value of. Lindsey. Agric. Science, 1894, 8, 98.

LEATHER is less soluble in pepsin than dried blood, but is rendered more soluble by steaming or treating with hot sulphuric acid; 1,000 lb. of sulphuric acid (50° B.), 300 lb. of powdered leather, 400 lb. of water, and 1,350 lb. of raw phosphate are the quantities recommended for the preparation of a manurial mixture. The presence of leather in a manure is best detected by testing for tannic acid.

—D. A. L.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar Industry, Progress in, for the Third Quarter of 1895. Dingler's Polyt. J. 1895, 298, [4], 88—95; [5], 114—115.

SOME years ago Sidersky published, for the determination of the density of masscutes, a method based upon the specific gravity of a solution of 20 grms. of syrup in 100 c.c. of water, the apparent dry substance being calculated from a table. This table is incorrect, as it was founded on Balling's old table constructed for Mohr cubic centimetres. This author (Bulletin de l'association des chimistes, 1895, 12, 565) has now, with the aid of the tables of Scheibler and Sidersky, constructed one in which the true cubic centimetre is the unit employed.

According to K. Farnstener, in a paper entitled "*The Weighing of Copper as Cupric Oxide in the Gravimetric Estimation of Sugar*" (Forsch. über Lebensmittel und ihre Beziehung zur Hyg. 1895, II. 235), the Allihn tube can be used for the oxidation of cuprous oxide. The pressure tubing (5 mm. internal diameter) connecting the filtration flask with the pump, is cut through at some convenient place near the former, and a piece of glass tube with drawn-out ends inserted. After the cuprous oxide has been filtered and washed in the usual manner, the connecting piece of glass tubing is withdrawn, the filter flask removed, and the narrow end of the Allihn tube introduced into the pressure tubing. The tube is then carefully heated, the pump still being in action, until the asbestos and cupric oxide commence to glow. After cooling in a desiccator, it is weighed. The author states that the method gives satisfactory results: a further examination seems desirable, since the usual troublesome reduction with hydrogen is avoided.

Studies on Alkalinity.—L. Jesser (Oesterr.-ungar. Zeits. f. Zuckerind. und Landwirth. 1895, 24, 497) has continued his extensive investigations on this subject. The results of his work show that complete control of temperature, time of separation, and quantity of lime added is necessary in the first as well as in the second saturation. The temperature must be regulated in every vessel, and reserve means of heating should be available.

According to Grobert's communication on *The Use of Surface Condensation for Vacuum and Evaporation Apparatus, System A. Schaad and E. Schiegl* (L'alcool et le Sucre, 1895, [3], 642), this system works well, notwithstanding the difficulties which usually beset innovations. Surface condensation is used to prevent the vapours from the syrup, containing volatile oils and other organic matter, coming into contact with the cooling-water. Pollution of the water by organic matter does not occur, and the volume employed is considerably less than when condensation is effected by injection. The tubes do not become incrustated

in the Schaad and Schiegel system: for although the water is hard, calcium salts are not precipitated, as the rise in temperature of the effluent water is gradual, and at no time reaches the temperature of the steam. This system is carried out in the Rossitz Sugar Manufactory (Moravia), and, from the results obtained, Grobert foresees—I. A simplification of the effluent question of sugar factories, as the volume of water used is less and its purification easier. II. More efficient condensation; thereby an increased vacuum. III. The condensation water is at a relatively high temperature, and, being absolutely free from sugar, it can be employed again for feeding the boilers, for diffusion purposes, and especially for the recovery of sugar from defecation-muds.

Use of Wood in Evaporating Apparatus.—Claassen (Dingler's p. J., 1895, 297, 184) has recommended for increasing the efficiency of the evaporating apparatus, a diminution in the cross section of the tubes by suspending suitable staves of wood (Rouleauxstäben) in a fixed position. The use of these staves in a triple-effect apparatus has been studied by Battut (Journal des fabricants de sucre, 1895, 35, No. 22) during the last campaign, and he found that although the evaporation was increased, and the formation of incrustation diminished, there were the following objections:—After the second usual cleansing of the triple-effect, a peculiar brown colouring of the syrup was noticed, an appearance considerably increased after the third cleaning, in which a boiling with potash-lye was included. The syrup from the thick-juice boiler contained appreciable quantities of invert-sugar, and the alkalinity had decreased. The staves were found to contain invert-sugar, colouring matter, and free hydrochloric acid; the latter was not removed by the alkaline treatment, and the result of its presence was the inversion and colouring of the juice during heating. Claassen (Zeits. des Ver. f. die Rübenzuckerind. des Deutsch. Reiches, 1895, 45, 517) states that Battut's (*loc. cit.*) objections are due to a different method of cleansing, and also to the fact that he placed staves in all three bodies of the triple-effect, when he (Claassen) advised they should be placed only in the first. Experiments have shown that hydrochloric acid does not penetrate quicker into used than into unused staves. Staves can be employed if they are confined to two bodies of a triple-effect; the whole apparatus should be cleansed by boiling first with soda, then, for a short time, with dilute hydrochloric acid ($\frac{1}{2}$ per cent.), and finally by careful rinsing out with water.

Details are given (Die deutsch. Zuckerind. 1895, 20, 1346) on the use of wood in a Yaryan apparatus at the Makaweli Factory (Hawaii).

Steam Engines in the Sugar Factory.—Strakoseh (Oesterr.-ungarische Zeits. Zuckerind. und Landwirth. 1895, 24, 524) states that the most important question in this direction is the replacement of the full-pressure steam engines still frequently found in sugar factories by those of the economical modern expansion type.

Lach (Oesterr.-ungarische Zeits. f. Zuckerind. und Landwirth. 1895, 24, 703) has carried out Soxhlet's refining process on a manufacturing scale, and was able to work with nearly saturated sugar solutions. For an input of 1,000 meter-centners, a filtering surface of 150 sq. m. of filter press and 75 sq. m. of Swoboda filter was required. According to the quality of the input, the filtration takes from 6—18 hours. The filter medium consists of kieselguhr and sawdust, which can be easily cleaned and used again, thus reducing expense to a minimum. Low-quality sugars may be worked up by repeatedly passing the "cleare" through mechanical filters.

The Use of Tollen's Formaldehyde Lamp in the Sugar Industry.—Tollens (This Journal, 1895, 592), having constructed a simple lamp which, by the incomplete combustion of methylalcohol, produces formaldehyde, Herzfeld (Zeits. des Vereins f. die Rübenzuckerind. des Deutsch. Reiches, 1895, 45, 529) has made some experiments with refined sugar solutions, and is of opinion that the lamp would be of service in disinfecting storing-places where sugar has gone bad, and in preventing the inversion of sugar solutions by fungoid growths.

The Purification of Effluent Water by Oxidation, and its Sterilisation by Light.—Grobert (L'alcool et le Sucre,

1895, 3, 110) divides his process into purification and sterilisation; the former takes place in two stages—preliminary cleaning, and oxidation. The water is conducted into convenient reservoirs and mixed with milk of lime (in combination with a metal salt in some cases, especially in sugar factory effluents) until feebly alkaline. The clear water is removed by filtration or decantation, and is then ready for oxidation, which must take place quickly and in the cold. Permanganates are best suited for this purpose, as they give no poisonous deposit, are easy to work, and comparatively cheap. The water containing the products of oxidation in suspension, is well aerated and allowed to settle in a reservoir. For the purposes of separation it is best to lead the water into a basin provided with a filtering dam. The centre of this dam consists of vertical layers of different-sized gravels held together by fascines and piles; the head is prepared of beaten earth or turf. Working with this system, it is possible to filter 10 sq. m. in 24 hours on each cubic metre of the basin. The filtered water is clear, only slightly alkaline, and free from lime. The dead micro-organisms are left behind in the deposit, but to ensure their complete absence the author exposes the water to the action of direct or reflected sunlight in shallow basins, the superficies being changed as frequently as possible. The appliances being the same as for the above-mentioned aeration.—J. L. B.

"Greying" of Raw Sugar. Munier. D. Zuckerind. 1895, 20, 1744.

The author considers that this coloration is caused by the presence of double sulphate of iron and potassium, and that the sulphur of this double salt principally arises from decomposed albumin. It is therefore of importance that the albumin should be completely precipitated.—J. L. B.

Sugar Beet, Manuring with Potash Salts. H. Bodenbender and N. Rydlewski. Blatt. f. Zeckerrübenbau. 1894, 1, 259—262.

The manuring with potash salts exerted no effect either on the yield of sugar beet or on the quantity of sugar therein, hence it is inferred that potash was not required on the soil of the experimental plots. More alkaline chlorides were found in the beet heavily manured with kainite; but no relationship was observed between the proportion of alkaline chlorides and the quantity of sugar in the roots.

Saccharine Syrups or Liquids, Improvements in the Method [Electrolytic] of and Apparatus for Purification of. G. Gin, Paris. Eng. Pat. 22,568, Nov. 21, 1894.

The process consists in purifying the syrup by the addition of (preferably) basic aluminate of calcium containing 4—6 equivalents of calcium, at about 80° C., to precipitate albuminoids, cellulose, pectin bodies, certain organic acids, and phosphoric acid, magnesia, iron oxides, &c. The syrup is then passed through a series of electrolysing troughs, wherein the dissociation of the impurities is effected by the aid of neutral electrodes. In the upper portion of each compartment, a separation and removal of the dissociated bases and acids is brought about by the passage of an electric current, partly through soluble anodes and partly through neutral anodes. It is found economical to divide this separation process into two operations, the acid liquid

from the soluble anodes being employed as re-agent in the second operation. Finally, the eliminated liquids are subjected to electrical osmosis for the recovery of the small portion of syrup that had diffused through the diaphragms in the preceding stages. Polarisation of the electrodes is obviated by blowing a current of air at intervals over the face of the electrodes to remove accumulations of gas and solid deposits.—C. S.

Boiling and Concentrating Apparatus [Sugar, Gums, &c.], *Improvements in*. T. Moore, Bristol. Eng. Pat. 23,396, Dec. 3, 1894.

This apparatus is designed for boiling and concentrating solutions of sugar, gums, mucilages, and the like by means of superheated steam, the superheating being effected preferably by the aid of molten metal surrounding the steam pipes. In order to counteract back pressure, an exhaust condenser or pump is employed to draw the steam through the liquid. The steam may be generated in a boiler or in the superheater, and may be passed through a coil or jacket in the boiling pan or be blown direct into the solution.—C. S.

A Carbonaceous Absorbent, An Improved Manufacture of. H. Albert, Biebrich-on-Rhine, Germany, and London. Eng. Pat. 138, Jan. 2, 1895.

SAWDUST, quinine waste, vine twigs, grape cake, or generally any suitable vegetable matter or by-product, is carbonised *in vacuo* at a stated high temperature, and the product, after being washed, is put through filter-presses and dried. This product is stated to have certain advantages over kieselguhr as an absorbent. 100 parts of it absorb 225 parts of phosphoric acid of 60° B., or 235 parts of sulphuric acid at 60° B., to form a solid mass. The absorbent charged with phosphoric acid, when used to precipitate albuminous matter from syrup, retains the colouring matter, leaving a "sugar solution as clear as water."—E. S.

Drying Waste Vegetable Substances, Improved Process for [Fodder]. P. Schottländer, Breslau. Eng. Pat. 2440, Feb. 4, 1895.

MAKING use of the osmotic properties of the vegetable cell, the inventor proposes to replace the superfluous moisture in waste vegetable substances by solid matters (in solution) of a suitable nature for increasing the value of the substance as fodder. The dissolved matters are made to circulate through successive vessels containing the substance under treatment, on the counter-current system, and when complete saturation has taken place, the excess of liquid is removed by pressure.—C. S.

Sugar, Improvements in the Manufacture of. W. P. Thompson, Liverpool. From H. A. J. Manoury, Paris. Eng. Pat. 3049, Feb. 12, 1895.

THE idea on which this invention is based is to regulate the composition of the massecuite, by means of added molasses in such quantity that, when all the water has been evaporated (except the 7 per cent. requisite for maintaining sufficient fluidity to allow of easy treatment in the centrifugal machine), the liquor surrounding the crystals has the same or a lower quotient of purity (0.69 for beet-root molasses, and as low as 0.40 for cane sugar syrup) than that of the molasses, a condition indicating the removal of all extractible sugar. Owing, however, to the necessity of centrifugal treatment at a lower temperature than that of the boiling pan, it becomes essential to increase the amount of added molasses by a quantity sufficient to redissolve the precipitate resulting on the cooling of the massecuite.—C. S.

Pure Saccharates, Improvements in and connected with the Production of. P. B. Hårje, Örtöfta, Sweden. Eng. Pat. 16,017, Aug. 26, 1895.

To obviate the waste resulting from the ordinary process of washing saccharates, and improve the quality of the finished product, the inventor proposes to substitute for the usual washing liquid a saturated solution of pure saccharate of the alkaline earth containing 0.1–1 per cent. of sugar,

and 0.3–1 per cent. of lime (CaO). In the case of barium and strontium saccharate, the proportions will be 0.2–1 per cent. of sugar, and 3–8 per cent. of barium hydrate, or 0.2–2 per cent. of sugar and 6–14 per cent. of strontium hydrate. The washing liquid is economised by using it over again, the final washings being effected by the purest liquid.—C. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

Isomaltose. E. Fischer. Ber. 23, 3024–3028.

SOME years ago the author found (Ber. 23, 3687) that a disaccharide (isomaltose) resulted from the action of strong hydrochloric acid on glucose. It was characterised by means of its osazone. Subsequently, Lintner announced that he had found isomaltose in beer, and he also described its presence amongst the products which result by the hydrolysis of starch, a statement which has recently been refuted by Ling and Baker, and Brown and Morris. Ost asserts (this Journal, 1895, 877) that the synthetic isomaltose is impure maltose.

The author has again examined the disaccharide, and finds that it differs in a very marked manner from maltose in its unfermentability by yeast, and in its stability towards the yeast enzymes.

Isomaltose was freed from glucose by fermentation with beer yeast, and the resulting product purified by dialysis. It gave an osazone, which on crystallisation from ethylic acetate, yielded nodular yellow aggregates of crystals, melting at 158°, and which, when dried at 100°, contained 10.27 per cent. of nitrogen, an amount which is about 0.5 per cent. below the calculated.—J. L. B.

Fermentation Industries, Advances in Biological Control of, by the Aid of the Microscope. P. Lindner. Journ. Fed. Inst. Brewing, 1, 547–557.

AFTER giving a historical survey of this subject, the author describes the following modification of Hansen's fractional culture method for yeast analysis and for the examination of air and water. Drops of a culture, which has been conveniently diluted with wort or sterilised water, instead of being introduced into flasks containing wort, are caused to fall upon the dry inner surfaces of two sterilised Petri's dishes. 50 drops are placed in each, and the dishes brought together with their inner surfaces facing. At the end of two days yeast spots may be found in the drops. These can be examined with medium powers, and it is only in the case of very small cells that culture in a special microscopic preparation is necessary. They moreover dry up quickly when exposed to the air, and furnish a preparation which lasts for months and can be used at any time for examination. In the case of wild yeasts, free aëration in the drop cultures often causes sporulation similarly to culture on gypsum blocks. The flocculent races of yeast are easily distinguishable from the non-flocculent varieties.

In order to determine the kind of growth of a beer on the lager vat, the author employs the method of "small drop cultures." A sharp-pointed, sterilised pen is dipped into the sample of beer. From 30–40 fine strokes 2 mm. long are drawn side by side on a sterilised cover glass, which is then placed over the well of the slide glass, a layer of vaseline being smeared round the glass ring, so that the junction is air-tight. The cells soon commence to germinate on the cover glass, and on the following morning round each mother cell may be seen some 20 daughter cells. If these are left undisturbed, they rarely become detached from their original position, and consequently the growths seldom become mixed. By examining the strokes, the author is able to count how many groups of wild yeasts there are in comparison with the normal yeasts. In such a culture, cultivated yeasts exhibit large, healthy, completely circular cells, with granular contents; the exhaustion of nourishment causing hardly any diminution in the size of the younger cells. The cells of the secondary yeasts are, however, smaller, and there is in them a lack of uniformity; although the nutrient solution is almost exhausted, daughter cells still continue to develop, whilst immature

and weak cells are cast off by the mother cell. The author also describes the examination of tun worts and pure water.—J. L. B.

Bacterium Aceti Hansen and Bacterium Pasteurianum Hansen, the Influence of Temperature on the Growth of. F. Lafar. *Centr. bl. für Bact.* 1895, 1, 129

EXPERIMENTS are here described which show that *B. Aceti* can grow at temperatures of 8–10° C., *B. Pasteurianum* giving no sign of activity at this temperature. The former can grow at still lower temperatures, and indeed flourished vigorously at 4° C.—A. L. S.

The Removal of Wild Yeasts from an Infected Pitching Yeast by the Natural Method of Pure Yeast Cultivation. A. Munsche. *Wochenschr. f. Brauerei*, 12, 1895, 598–601.

THESE experiments were carried out in a brewery.

A pitching yeast was prepared of eight parts of brewery yeast and one part of wild yeast. The wort was pitched at 7° R.; after well rousing, a sample was taken and examined by Lindner's method of drop cultivation, and the yeast was found to contain 14.3 per cent. wild yeast.

After standing 42 hours, the wort was pumped into another vessel, allowing the sediment to remain behind. The fermenting wort was then heated to 10° R. and three large glass vessels were immersed in it which were removed for examination on the second, third, and fifth day.

The yeast in the first contained 0.5 per cent. of wild yeast, that in the second was 16 mm. high, of which 6 mm. corresponded to that in the first vessel; the remainder contained 1.5 per cent. of wild yeast. The yeast of the third dish contained in the upper 2 mm. 5.5 per cent. of wild yeast. It is thus evident that a separation has already taken place.

The yeast from the bottom of the vat was collected, and on examination was found to contain 4.3 per cent. of wild yeast. This yeast was suspended in water and allowed to deposit, when the water was drawn off. This was repeated six times. A vat was pitched with this purified yeast; after well rousing, the wort was examined and the yeast was found to contain only 0.9 per cent. of wild yeast. The pitching temperature was 7.5° R. and rose to 9.5° R. in four days. After drawing off the fermenting wort, the sedimentary yeast was found to contain absolutely no wild yeast.

Another experiment confirmed these results.—A. L. S.

Diastase, Chemical Nature of. T. B. Osborne. *J. Amer. Chem. Soc.* 1895, 17, 587–603.

DIASTASE prepared by the usual methods contains the greater amount of the proteid matter of the malt, together with a large amount of carbohydrates and salts. The author precipitated the diastase and proteids by saturating an aqueous malt extract with pure ammonium sulphate. This precipitate was dialysed in water until most of the sulphate had been removed and the proteid largely dissolved. The insoluble residue, consisting chiefly of globulin, was filtered off, and the filtrate saturated with ammonium sulphate; the resulting precipitate was dialysed in water, whereby most of the globulin was separated, and after filtration, the filtrate was dialysed into an equal volume of alcohol of sp. gr. 0.84. After 24 hours, precipitate 1 had separated and was filtered off. The filtrate was dialysed into alcohol of the same strength and precipitate 2 obtained. Precipitate 3 resulted by dialysing the filtrate into stronger alcohol, and precipitate 4 in a similar manner. The filtrate from this, on the addition of a large quantity of absolute alcohol, yielded precipitate 5.

Precipitate 1 was not wholly soluble in water. The soluble portion was dialysed in water, then in strong alcohol, when it yielded a substance with a diastatic power of 30 on Lintner's scale. The insoluble portion was extracted with a sodium chloride solution, filtered, and the filtrate dialysed; it then had the properties of globulin, and a very low diastatic power. Precipitate 2 was treated with water, dialysed in the same medium, and then in alcohol, for 24 hours. The proteid, when precipitated with strong alcohol, was soluble in water, and had a diastatic power

of 75. The portion insoluble in water was similar to the residue of 1. Precipitate 3 was subjected to the same treatment; it had a diastatic power of 222. Precipitate 4, similarly treated, yielded a substance dissolving to almost a clear solution in water, and having a diastatic power of 600. Its composition was: Carbon, 52.59 per cent.; hydrogen, 6.72 per cent.; nitrogen, 16.10 per cent.; sulphur, 1.90 per cent.; oxygen, 22.78 per cent. Precipitate 5 was completely soluble in water, had a diastatic power of 60, and consisted chiefly of proteose. The author concludes that diastase is a true proteid, and is therefore either an albumin, a combination of albumin with a proteose, or a proteose. Inasmuch as those precipitates consisting of proteose have only a slight diastatic action, it would appear that the diastatic enzyme is most closely related to albumin.—J. L. B.

Sulphured Hops, Disadvantages of. *Wochenschr. f. Brauerei*, 1895, 912–913.

THE influence of sulphuring on hops is by no means properly understood by the average brewer; some, indeed, consider hops to be improved by the process, and purchase sulphured hops accordingly. The advantages, however, are entirely on the side of the dealer, enabling him to palm off an inferior article at a superior price. The disadvantages (to the brewer) may be summed up as follows:—

1. Sulphured hops are sent out in a much moister condition (10 per cent. more water) than is permissible in the case of properly cured unsulphured hops.

2. The process is employed to hide real and serious defects. Musty, discoloured hops are renovated and restored to a semblance of good fresh hops.

3. Hops from various sources, no matter how different in colour, &c., may be mixed and made apparently uniform by sulphuring.

4. The sulphur abstracts from hops a portion of their fine aroma, whilst the sulphuric acid formed by slow oxidation, unfavourably influences the fermentations and the delicate flavour of the beers.

The brewer is, therefore, strongly recommended to purchase his hops direct from the grower, and not to lay too much stress on a fine, uniform appearance of the article—too frequently merely the result of sulphuring.—H. T. P.

Pasteurisation of Beer. Can Beer be rendered Practically Sterile without Alteration in Flavour and Composition? H. van Laer. *Le petit J. du Brasseur*, 1895, 391.

THIS question is answered in the affirmative, provided suitable conditions be adhered to. The temperature and duration of pasteurisation required, depend on the nature of the beer, the number and nature of the organisms contained in it, and on the time the beer is to remain sound afterwards. In general, however, a temperature of 60° C. suffices to render beer practically sterile. In case of bottom-fermentation beers, this temperature should be reached in about 20 minutes, and maintained for 15 minutes longer before cooling, &c. As regards top-fermentation beers (pale ale), the heating should be more gradual (to 60° C. in about 50 minutes). The essential point, however, is that the beer must contain a good excess of carbonic acid. The following *modus operandi* is, therefore, suggested:—

1. Saturation of the beer with artificial carbonic acid.
2. Filtration.
3. Transfer to the steriliser under isobarometric pressure.
4. Pasteurisation and cooling.
5. Transfer to casks, &c., under isobarometric pressure.

In addition, any pipes which the beer must traverse after pasteurisation should be steamed. As regards sterilisation of storage vessels, it suffices to wash bottles with water at 80° C. Casks, if freshly enamelled, may be used straight away; with others, treatment with steam or hot water is believed to be sufficient. It must be mentioned that the author employed in his experiment a steriliser *silver-plated* internally. This was filled with beer to within 2 per cent. of its volume, and *hermetically* closed during the whole duration of pasteurisation.—H. T. P.

Formaldehyde in the Brewery, Its Use as a Germicide.
Windisch. Wochenschr. f. Brauerei, 1895, 909—910.

CERTAIN results (Amer. Brewers' Rev. No. 2, Aug. 1895) are quoted, according to which the use of "formalin" (a strong solution of formaldehyde in water) must be entirely condemned, "partly on account of its poisonous properties, partly because it produces in beer, even when added in small proportions, gluten-turbidity, and an objectionable flavour." The author points out that the above conclusion is misleading, since the legitimate function of formaldehyde is that of a disinfecting agent. Formaldehyde vapour (this Journal, 1895, 379—380), even when largely diluted with air (as obtained by the incomplete combustion of methyl alcohol), exerts a powerfully destructive action on germs in general, and on mould-spores in particular; and affords a cheap and ready means of disinfecting storage cellars, cooler and refrigerator rooms, plant, &c., from which the vapour is afterwards readily removed by ventilation or washing. In this connection, Trillat suggests that the atmosphere over coolers and fermenting tuns should be sterilised by means of formaldehyde vapour, in order to preserve the worts from infection. In solution, formaldehyde appears to lose much of its power, and, according to Trillat, at least 10 grms. per hectolitre must be added to beer to check the development of the lactic and butyric ferments. Its use as an antiseptic is, therefore, evidently beyond question.—H. T. P.

"Flour Dressing" in its relation to Beer. T. A. Glendinning. Journ. Fed. Inst. Brewing, 1, 558—570.

DIASTATIC dressing continues the conversion of the starch products formed during mashing. It has been stated that flour dressing exerts a mechanical action upon the yeast produced. To show that this assertion is not correct, the author carried out the following experiment:—Two similar worts were fermented under the same conditions; the first was dressed with wheat flour, the second with a filtered aqueous extract of an equal weight of the same flour. The fermenting worts were well roused, and the following conclusions drawn from the analytical results:—The rate of attenuation was about the same in each case, the two yeast crops were almost identical, whilst the quantity of sludge left in the fermenting vessels after racking did not materially differ. Flavour, brilliance, and condition were alike in the resulting beers, and analyses made after racking showed them to be the same in composition. If dressing be added at an early period of primary fermentation, the beers tend to rack at lower gravities than do non-dressed beers. A considerable difference is noticed in the behaviour of dressed and non-dressed beers when subjected to the "forcing test." If any fermentable matter be present, both classes of beer begin to ferment vigorously at 75°—80° F. When this action ends, only a slight fermentation, which soon ceases, is observed in dressed beers; the non-dressed beer ferments steadily, and will continue to do so after the expiration of the usual time for forcing. There are marked differences in the deposits from the forced beers, the yeast cells from a dressed beer being small and shrivelled, and the number of bacteria greater than in a deposit from a non-dressed beer.

In a discussion which followed the reading of this paper, J. Heron said that he had found flour dressing useful in arresting boiling fermentations, more especially those in which the attenuation of the fermenting wort ran down very low. This was not explained by the author's statement that the effect of dressing was to hydrolyse the unfermentable constituents of the wort. E. R. Moritz stated that there were two kinds of boiling fermentation, one arising from under- and the other from over-saccharification. In both cases the action of dressing was beneficial; in the first because the diastatic action reduced the viscosity and made the composition of the wort normal with regard to starch transformation products; in the second, because the effect of the dressing was to aerate the wort, and to cause the expulsion of carbon dioxide, consequent upon the rousing-in of the dressing.—J. L. B.

Refrigerating Machinery, New Improvements in.

Drying Waste Vegetable Substances, Improved Process for.
P. Schottländer, Breslau. Eng. Pat. 2440, Feb. 4, 1895.

See under XVI., page 43.

Charging Liquids [Beer, &c.] with Gas, and Apparatus therefor, Improvements in or relating to. A. J. Boulton, London. From A. M. Hofmann, Chicago, U.S.A. Eng. Pat. 2039, May 17, 1895.

The salient points of this invention are the charging of beer and other liquids with carbonic acid gas (previously incorporated with a portion of the liquid) in a mixing chamber situated between the pumping and storing apparatus. The latter contains air or gas under a counter-pressure for preventing the escape of the gas imprisoned in the charged liquid, and the vessel is not only completely filled, but surcharged with the liquid so as to cause an actual compression of the same, equivalent to the production of about 150 lb. pressure in the holder. In racking off the contents of the holder, both the latter vessel and the racking apparatus are connected with a low tension back-pressure reservoir to keep the gas from escaping during the process.—C. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY AND WATER PURIFICATION, DISINFECTANTS.

(A.)—CHEMISTRY OF FOODS.

Germ-free Drinking Water, Preparation of, by means of Chloride of Lime. Dr. Bassenge. Zeits. für Hygiene, 1895, 227; Proc. Inst. Civil Eng. 1895, 123, 33—34.

THE disinfecting properties of chloride of lime have been frequently investigated, and a brief account is given of the opinions expressed by those who have previously dealt with this subject. Traube has pointed out its probable value for the production of a germ-free drinking water, and has proved its utility by practical experiments. His tests, however, were not conducted with pathogenic germs, though he concluded from his experiments that this substance, used in the proportions which he advocates, would be fatal to all kinds of bacilli.

The author sums up the facts established by him as follows:—

(1.) In order to render water which is highly polluted with pathogenic bacteria germ-free, it suffices to add to it for 10 minutes 0.0978 gram. of active chlorine per litre, which is about equivalent to 0.15 gram. (three parts per 20,000) of commercial chloride of lime. If the time under treatment be extended, say, to two hours, 0.0108 gram. of active chlorine is sufficient.

(2.) The superfluous chlorine not needed for the disinfection can be reduced by means of calcium bisulphite, which leads to the formation of a scanty precipitate of calcium sulphate. Water treated in this way is quite innocuous, acquires no unpleasant taste, but increases in hardness. It can be partaken of throughout lengthened periods without injury to health, since, for the foregoing chemical treatment, no substances are added beyond such as are usually present in potable waters.

(3.) It does not require any chemical test to determine whether all the chlorine has been removed, since this fact can readily be ascertained by taste and smell.

(4.) This process of safely preparing by chemical means a germ-free drinking water can be easily carried out, and possesses from certain aspects a most important practical significance.

Trades Waste, Treatment of. W. Naylor. Proc. Inst. Civil Eng. 1895, 123, [Part 1.].

Methods of treating the waste liquors from the following industries are described:—(1) Calico-bleaching, -dyeing, and -printing. (2) Wool-washing and -scouring. (3) Paper-making. (4) Tanning. (5) Alkali- and soap-making, and (6) Iron-galvanising.

Calico-bleaching, -dyeing and -printing. The analyses given below indicate the general nature of the various effluent liquors from a calico-bleachworks, in which the lime and soda-ash process of bleaching is followed.

The plant now generally used for dealing with these liquors consists of settling tanks and filters. That designed and constructed for Stanning and Sons, of Leyland, has been in successful operation some time. The bleach- and dye-liquors, along with all the wash-waters, enter the mixing-channel together and are treated with lime and aluminoferric sulphate. Thence they pass to the precipitation-tanks, in which subsidence of the suspended matters takes place. The ferric and aluminium hydroxides, besides inducing the deposition of suspended matters, assist in clarifying the effluent liquors by combining to some extent with some of the colouring matters present.

A continuous flow of the liquors into the tanks is found to give the best results, this being probably due to the fact that the suspended matters in bleach- and dye-liquors aggregate when slightly agitated.

The almost clear liquor is conducted away from the top of the tanks by floating-arms, and the sludge is removed by a Shone ejector, into which it gravitates. A volume of 500,000 gallons is dealt with daily, this being the combined capacity of the tanks. The nearly clarified liquors are generally run into the river direct, but if required for further use, they are collected in a storage reservoir. In the latter case, they are pumped from the sump on to cinder-filters, which deliver the water into the reservoir. Thence pipes convey it from a well to the various departments of the works.

The filter-beds are about 5 feet deep and are made of furnace-clinkers. The dissolved solids are largely eliminated by them, as is shown by the following analyses:—

	Dissolved Solids.			Suspended Solids.			Total Solids.		
	Volatile.	Mineral.	Total.	Organic.	Mineral.	Total.	Mineral.	Organic.	Total.
	Parts per 100,000.								
Untreated liquor.....	41	86	130	24	12	36	98	68	166
Tank liquor.....	40	92	132	92	40	132
Filtered liquor.....	10	56	66	56	10	66

The quantity of aluminoferric sulphate used per day amounts to 166 lb. About 17 tons of sludge, containing 95 per cent. of water, are produced, but of this only about 33 tons are retained, the remainder passing away in the liquors.

The wet sludge is lifted by the ejector into earth drying-pits, from which it is carted away when dry.

Dried at 100°, the sludge consists (per 100 parts) of:—Organic matter (19.6 parts), silica, &c. (38.5), calcium carbonate (31.1), alumina (3.2), ferric oxide (7.3). It has no value as either fuel or manure.

The Mather-Platt system of softening water (this Journal, 1891, 511) has been extended to the treatment of dyers'

and bleachers' waste waters. Its principal advantages are:—The quick and intimate intermixture effected by it of the precipitants and liquors under treatment; the ease and accuracy with which precipitants can be used and their results tested as regards alkalinity, acidity, or neutrality; and the reduction in the amount of precipitant required owing to the clarifying action of the sludge already formed.

The Candy tank is well adapted for the economical removal of suspended matters from liquors which are only slightly polluted, and which do not require filtering. The liquors are fed into the tank at the bottom by down-pipes, the inlets being laid at semi-tangents to avoid disturbance

of the sludge already deposited. The tank has a flat bottom, from which the sludge is siphoned off by a perforated pipe, moved over its surface by a winch. The sludge is delivered about 2 feet below the level of the water in the tank and is of a satisfactory consistency.

Indigo-dyeing.—At the works of the Pincroft Dyeing and Printing Company, Adlington, Lancashire, the waste liquors containing indigo in suspension are passed into precipitation-tanks, receiving on the way between 10 and 15 grains of lime per gallon. The precipitated indigo is raised by an ejector from the bottom of the tanks, and blown into the dye-vats for use again. The liquors contain, before treatment, 0.4 part of indigotin per 100,000, and are of a deep blue colour; after treatment they are clear, and contain little objectionable organic matter.

Wool-washing.—At the works of Thomas Biggart, of Dalry, Ayrshire, the recovery of the grease and potash from the liquor produced in wool-scouring is effected in the following manner:—The suds from the first bowl, containing about nine-tenths of the grease and potash, after standing about 12 hours to ensure deposition of the sand, are evaporated in a pan until the liquid attains a syrupy consistency. The resultant liquid is then cooled in shallow iron trays, the grease which collects on the top being removed at intervals. The semi-liquid residue is calcined in a brick oven, the heat produced from it being used to assist in the evaporation. A crude carbonate of potash is thus produced, which after being completely carbonated, is boiled to dissolve out the potash salts. The solution is concentrated to 100° Tw., the potassium sulphate and chloride crystallising out on cooling. The quantity of fuel required is about 1 ton for 1,500 gallons. The potassium carbonate and grease obtained are sold.

In a recent type of machine, that of Emile Richard-Lagerie, of Roubaix, the wool is subjected successively to the action of liquors of diminishing strengths, the last being clear water. The liquors, after having passed through the wool, are pumped for re-distribution into tanks, until they attain a density of 1.07, when they are evaporated, and the residues calcined for the manufacture of potassium carbonate. Each machine is capable of dealing with about 8 tons of wool per 24 hours. The furnaces consume 1 cwt. of coal per cwt. of potash produced.

The grease is extracted from the suds at the works of Alf. Matte and Co., Roubaix, by a mechanical process of "battage." The suds are, by means of a rotary agitator, beaten into a froth, which carries to the surface the fatty matters. The latter are skimmed off into conduits by a mechanical scraper, and are forced by a steam extractor into a wooden tank, in which they are heated to 60° and treated with sulphuric acid in the proportion of 1 lb. to 100 gallons. The acid is then removed by washing and the grease is filter-pressed.

Wool-scouring.—In the establishment of Thomas Fox, at Wellington, Somerset, the soapy liquors are led into six acidifying tanks and treated with sufficient acid to liberate the fatty acids, which on separation along with the wool-fat, are drained on sawdust filters. They are afterwards taken off and purified by distillation for conversion into soap again.

The dilute acid from the acidifying tanks is pumped into intermediate storage tanks for further settlement, after which it gravitates into the precipitation tanks, and is treated with the general waste waters from the works by aluminio-ferrie sulphate and lime.

Paper-making.—The effluents from paper mills are effectually purified by the same methods and means as cotton bleachers' effluents. When treated with ferrous sulphate and lime, deposition of solids takes place quickly, and a clear, supernatant liquid is obtained.

At Peebles' Mill, Church, Lancashire, the precipitate obtained with aluminio-ferrie sulphate and lime is collected and pressed, and, owing to its containing a considerable amount of fibre, is used, after being washed, for the manufacture of the coarser brown, or shop, papers.

Since the introduction of imported wood pulp, the volumes of waste liquors from paper mills have decreased largely.

Tanning.—Waste liquors from tanneries form probably the worst manufacturing pollution, containing, as they do, much organic, putrescent matter, which cannot be precipitated by ordinary means, if at all.

The plant in use at the works of W. and J. Sagar, of Colne, consists of two sets of tanks, along with screens and filters. The first set of tanks receives the washings of hides and the fermentation refuse liquors. From them the liquor passes, after settlement, through fibre-screens to a series of precipitation tanks, and thence, through an oxidising filter, to the river.

The second set of tanks receives the waste liquors from the lime pits. These, after settling, are filtered through layers of earth and ashes, which are so arranged as to enclose as much air as possible.

Alkali Works' Refuse.—In addition to the Chance sulphur recovery process, various expedients have been devised for the treatment of the immense quantities of tank waste lying about the country.

One of these consists in pumping the drainage liquors from subterranean channels on to a filter of iron oxide, then clarifying the more or less oxidised liquor by subsidence in tanks, and again filtering through iron oxide.

Another method, which is advantageously adopted where large volumes of waste liquor have to be dealt with, is to treat the liquor with a ferric salt and then to filter through sand or gravel.

Iron Galvanising.—The waste from this industry consists of either iron sulphates or chlorides, with free sulphuric or hydrochloric acid.

In the case of the iron sulphate waste, treatment with lime is adopted, the precipitated iron oxide being sometimes collected and used as a pigment.

In the case of the mixed ferrous and ferric chloride waste, excellent results are obtained with the Turner recovery process. The solution is evaporated, and the residue strongly heated, decomposition into ferrous-ferrie oxide, chlorine, and hydrochloric acid taking place. The chlorine is mixed with steam as it passes over the fire-bridge of the furnace, and is transformed into hydrochloric acid. This, along with that evolved as such, is led into a tower and condensed for use again. The recovered acid contains, on an average, 8.8 per cent. by weight of ferric chloride which volatilises with it from the decomposing furnace. The iron oxide obtained is of some value as a fettling for puddling-furnaces, for which it is sold.—E. B.

PATENTS.

Filtering Apparatus [Water], Improvements in or connected with. J. Pinfold, Aston, Birmingham. Eng. Pat. 695, Jan. 11, 1895.

The filter consists of a tank charged with filtering material to about one-third of its height, and special arrangements are made for collecting the filtered water, and for washing out or for sterilising the bed. The filtered water is collected by a number of gathering tubes placed at the bottom of the tank connected to a main duct leading to a discharge valve. The gathering tubes are provided on their top surface with a number of conical nozzles screwed therein, each nozzle having a convex fine wire gauze cover, and an internal spherical distributor or distributing plate. Instead of gathering tubes, a detachable chamber may be used, divided from the filtering tank by a plate having holes through which the screwed nozzles pass. When it is desired to wash out or sterilise the apparatus, the filter is run dry and water or steam passed upwards through the bed by means of the collecting tubes and nozzles, and the water passes away through openings in the tank just above the filter-bed to an annular pocket surrounding the vessel, and provided with a discharge valve. During the washing-out process the bed is agitated by vertical or inclined progs carried by a horizontal shaft joined to a vertical one, driven by worm-gearing from the exterior.—R. S.

Sewage Precipitation, New or Improved Method in. G. C. Purvis, Edinburgh. Eng. Pat. 20,366, Oct. 29, 1895.

THE sewage is first treated with carbon dioxide, or, if there be sulphuretted hydrogen present, with a mixture of that gas and sulphur dioxide, and then lime is added in very small excess, sufficient to render the liquid faintly alkaline to test papers.—L. A.

(C).—DISINFECTANTS.

PATENTS.

Diseases of the Vine and other Plants, A Composition for Treating. J. Y. Johnson, London. From L. Lasmolles and E. Fréchet, Paris. Eng. Pat. 360, Jan. 5, 1895.

COPPER sulphate, aluminium sulphate, and sodium bicarbonate are mixed together in suitable proportions. When the mixture is brought into contact with water in a suitable apparatus, carbon dioxide is generated, by the pressure of which the liquid containing in suspension basic carbonate of copper and alumina is sprayed on to the vine.—L. A.

Antiseptic and Disinfecting Compounds, applicable also for Washing Sheep and other Animals, and for the like purposes, An Improved. A. Pickles, Wakefield. Eng. Pat. 14,305, July 27, 1895.

THE first is a liquid mixture of castor oil, soap, and pyridine and the second is a powder made by mixing pyridine with powdered gypsum, chalk, or the like.—L. A.

Disinfectant Compound which may be used for Dipping Sheep, also as an Antiseptic for Purifying, Disinfecting, and General Detergent Purposes, An Improved. J. L. Wale, London. Eng. Pat. 18,223, Sept. 30, 1895.

COAL-TAR creosote, 40 parts; rosin, 20 parts; cresylic acid, 5 parts; olive acid, 5 parts; caustic potash solution (25° B.), 20 parts; eucalyptus oil, 5 parts; naphthalene, 5 parts; blended by heat.—L. A.

Disinfectant or Composition for Antiseptic, Disinfecting, Sanitary, and other Purposes, An Improved. H. Hiscott, London. Eng. Pat. 19,418, Oct. 16, 1895.

THE improvement consists in the preparation of a disinfectant in which phenols are present together with soluble fluorides, silicofluorides or borofluorides. Thus, any form of crude phenol is first mixed in the usual manner with melted rosin and a strong solution of caustic alkali, so as to form a clear fluid, a little cotton seed or cocoa-nut oil soap being added if required. The hot solution of the fluoride, silico-fluoride or boro-fluoride is then stirred in, not less than 10 parts of fluoride or 15 parts of silico- or boro-fluoride being added for every 100 parts of phenols.—L. A.

XIX.—PAPER, PASTEBOARD, Etc.

Retail Paper Trade in Relation to Composition and Permanence of Writing Papers. Mitt. k. k. Versuchsanst. 1894, 12, 295; 1895, 13, [5], 219.

THE paper-testing work of the German Government Testing Institution at Charlottenburg has, as is well known, resulted in a systematic classification of papers according to composition and physical qualities, which classification, officially adopted, now regulates in an important and increasing degree the general practice of the manufacturing and wholesale trade. Whilst it has been easy to enforce the adoption of papers of specified composition in State and public offices, it is pointed out that the general public (in Germany) employ paper entirely "at haphazard," even in writing documents of official and permanent value. With the view of forming a public opinion on this matter, the Institution has undertaken an investigation of the practices prevailing in the retail selling and buying of papers. The scope of the inquiry may be outlined as follows:—Writing papers were bought at 35 of the leading stationers of Berlin, under recognised descriptions, such as good writing paper, best foolscap, best official note, good "lasting" paper, &c.—all implying the requirement of paper of high quality.

They were bought in quantities of 10–12 sheets, and at the same time the price was obtained for the paper in quantities of 1,000 sheets.

The papers were then analysed and classified according to the standards of the Institution. The results are given in tabular form.

At the same time also the question of selling price was investigated, the papers purchased being independently valued by three experts, the valuation being set out in tabular form, and a column giving the ratio of selling price to the mean figure calculated from the valuations.

The tables given do not admit of abstraction, but the main results tabulated lead to the following conclusions:—Of the papers purchased as "of lasting quality," 17 per cent. only conform with such specification; of the remaining 83 per cent., 29 are papers which could be guaranteed for a few years' "life," under ordinary conditions of storage, and 54 are of the classes suitable only for ephemeral purposes.

The results of the investigation in reference to selling prices were even more surprising. They show unaccountable variations, the figures lying for the most part between from 2 to 80 per cent. in excess of the estimated "fair" price.

The Institution then carried out some months later a second investigation, which was an exact repetition of the first. The results, which are given in the 1895 vol., 222, substantially confirm those already obtained, i.e., about 70 per cent. of the papers purchased were altogether inferior to the specification of the purchaser. It is noted also that three of the papers contained "mechanical" wood pulp, and seven contained more than 15 per cent. of mineral (ash) constituents.

Again, a similar investigation was carried out on the retail paper trade of Leipzig, and the results were closely similar to the above.

The author (Herzberg) sums up the work of this self-appointed commission in the laconic remark: "the probability of obtaining on demand a high-quality paper is, in the better class of stationers' shops in Berlin, about 1 in 5."—C. F. C.

Paper-testing, Reports on. Mitt. k. k. Versuchsanst., Berlin, 1895, 232.

A. MAINLY an account of controversies which have arisen upon reports furnished by the Institution. Results of analyses having been called in question, the samples in question have been further investigated, and in all cases the original finding confirmed.

B, C, D, E. These sections likewise contain no matter of fresh import.

F. Is a note upon "Oxidising Constituents of Papers." In investigating a wrapping paper prepared by impregnating an ordinary thin paper with a mixture of volatile and non-volatile hydrocarbons (Ger. Pat. 74,180), the presence of an active oxidant was revealed. Papers treated with linseed-oil varnishes have given similar results, viz., the liberation of iodine from a solution of potassium iodide; and the oxidant has been identified as hydrogen peroxide (Nördlinger). It appears that either a drying oil or turpentine, which was probably used in the former case, can occasion the formation of hydrogen peroxide.—C. F. C.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Narcotic Extracts, their Preparation and Alkaloid-Content. F. Ranwez. Chem. Zeit. Rep. 1895, 19, 190.

In the preparation of extracts generally from fresh plants, very different results are obtained according to the mode of procedure. A brown or green product is obtained according as the plant extract is, or is not, filtered before evaporation, the former containing much more alkaloid than the latter. The degree of concentration to which the extract is evaporated before the addition of alcohol also largely influences the result; the smaller the yield of extract, the larger is the quantity of alkaloid.—A. C. W.

Phellandrene. O. Wallach. Lieb. Ann. 287, [3], 371—384.

Two modifications of phellandrene occur in nature—dextrophellandrene in eucalyptus oil and levo-phellandrene in oil of bitter fennel. Phellandrene combines with nitrous acid to form a nitroso-nitrite, which Wallach prepares as follows:—The raw Australian eucalyptus oil is distilled under reduced pressure, whereby polymerisation is prevented, and the fraction containing the largest amount of phellandrene is dissolved in petroleum spirit and treated in a freezing mixture with dilute sulphuric acid, followed by the gradual addition of sodium nitrite solution. Care must be taken that the temperature does not rise above + 4° C. The nitroso-nitrite separates, is strained off from the liquid, washed with ice-water, and dried between filter-paper. It is finally purified by washing with methyl-alcohol, solution in chloroform and precipitation by a mixture of ether and alcohol, when it is obtained in snow-white woolly masses of crystals, melting at 165° C., and in the pure condition it is fairly stable.

Sodium ethylate converts it into Peci's "nitro-phellandrene," $C_{10}H_{15}NO_2$ (Gazz. Chim. 1886, 16, 227), and by reduction in alcoholic solution with sodium, an amido compound, $C_{10}H_{19}NH_2$, a ketone, $C_{10}H_{15}O$, and an alcohol, $C_{10}H_{19}O$, were obtained.

By mixing the corresponding derivatives of the dextro- and levo-phellandrene, racemic inactive mixtures resulted, which proved to be identical with similar derivatives prepared by the author from Carvenone (Wallach, Ann. 277, 130—137). These reduction products are active modifications of tetrahydrocarvone, $C_{10}H_{17}O$, tetrahydrocarveol, $C_{10}H_{19}O$, and tetrahydrocarvylamine, $C_{10}H_{19}NH_2$.—H. I.

p-Bromaniline Sulphonic Acid and a New Method of Preparation of Benzoic Sulphinide [Saccharine]. H. Kreis. Annalen, 286, 377.

By modifying the method of sulphonation of *p*-bromacetanilide, the author has prepared the *p*-bromaniline sulphonic acid. By a second modification—heating with 50 per cent. of its weight of ordinary sulphuric acid at 170°—180°, a quantitative conversion into the *o*-sulphonic acid is realised. The latter was converted by Sandmeyer's reaction into *p*-bromcyanobenzene-*o*-sulphonic acid; this into the anhydrochloride, from which the sulphonamide was obtained and readily converted into the corresponding benzoic-sulphinide—

An exactly parallel synthesis of the sulphinide—

was carried out by first debrominating the *p*-bromaniline-*o*-sulphonic acid and proceeding as indicated above.

—C. F. C.

Saccharine, Preserving Action of. Burkard and Seifert. Chem. Zeit. 19, 1895, 220.

The antiseptic power of absolutely pure saccharine was shown to be five times less, and that of the so-called "saccharinum purum" (300 times sweeter than sugar)

eight times greater, than that of salicylic acid. This, however, is of little importance in connection with its preserving properties. For instance, 3 grms. of salicylic acid are added to 1 hectol. of beer to prevent after-fermentation. The corresponding addition of 15 grms. of "absolute saccharine" would make the beer unpalatable through extreme sweetness.—J. R.

Drimys granatensis, L., Bark and Leaves of. O. Hesse. Annalen, 286, 369.

FROM observations of Schuchardt recently cited in the Pharm. J. and Trans. [3], 24, 169—170, this plant is described as "cotoin-yielding." After investigating the bark, the author concludes that it contains no cotoin whatever. He succeeded only in isolating an inert substance, Drimin, $C_{13}H_{14}O_4$.

From the leaves an alcoholic compound was extracted, with an empirical formula, $C_{25}H_{35}O_2$, which the author names Drimol. It melts at 73° 5'; yields an acetate— $C_{25}H_{37}(C_2H_3O)_2$ of m.p. 42° 5'; and an iodide, $C_{25}H_{37}IO$ on boiling with hydriodic acid (1·7 sp. gr.).—C. F. C.

Poisonous Vanilla. K. F. Töller. Pharm. Central-Bl. N.F. 1895, 16, 450.

THE author considers that ptomaines may be the cause of the poisonous results recently observed to follow the use of vanilla. The method of packing in tightly-bound moist bundles would, without doubt, favour decomposition. He recommends that the vanilla should be dried by desiccating agents, as in his cold-drying apparatus, and then preserved in air-tight glass cylinders. The aroma is retained by this treatment.—A. C. W.

Vanilline, Improvements in the Manufacture of. J. Y. Johnson, London. From F. von Heyden's Nachfolger, Radebeul, Germany. Eng. Pat. 1624, Jan. 23, 1895.

VANILLINE may be prepared by the electrolytic oxidation of an alkaline solution of iso-eugenol in a divided cell. The anodic compartment is charged with 15 per cent. iso-eugenol solution in excess of caustic lye, and the cathodic compartment contains 10 to 20 per cent. soda solution. The electrolysis proceeds best at 60° C., a current of about 6 amperes being passed, with an E.M.F. of 5 volts. The anodic liquid, on completion of the oxidation, is acidified, extracted with the ether, and the vanilline separated from the ethereal liquid by agitating with alkaline bisulphite.

J. W.

Saccharin or Compounds thereof, Improvements in Manufacture of, and in Production and Treatment of Materials for Use therein. C. Fahlberg, Salbke-Westerhüsen, Germany. Eng. Pat. 10,955, June 1, 1895.

THE methods for the manufacture of saccharine hitherto employed were attended with considerable loss of material, from the fact that the para-toluene sulphonic acid, formed simultaneously with the ortho-toluene sulphonic acid, had to be subjected to several costly operations along with the latter. It is now found that the two isomeric acids may be largely separated by means of their magnesium salts, the para-compound being much less soluble than the ortho-compound. The magnesium ortho-toluene sulphonate is treated with sodium carbonate, the sodium salt being thus formed, and the magnesium carbonate simultaneously produced being available for the formation of more magnesium toluene sulphonates. The solution of the sodium salt is now oxidised with potassium permanganate, the liquid concentrated, and the acid sodium sulphonybenzoate— $COOH.C_6H_4.SO_3ONa$, precipitated by means of hydrochloric acid. The precipitate, after being dried, is converted into the ester $COOR.C_6H_4.SO_3ONa$ by the aid of alcohol and gaseous hydrochloric acid. This ester, on treatment with phosphorus pentachloride or oxychloride, yields the ester-chloride: $COOR.C_6H_4.SO_2Cl$, which, on treatment with gaseous ammonia and ammonium carbonate, and subsequent

saponification with an alkaline carbonate, yields an alkaline salt of benzoic sulphinate together with some alkaline para-sulphamino-benzoate. After all the ammonia has been expelled, the concentrated solution is treated with a small quantity of potassium permanganate to brighten the colour, and the para-sulphamino-benzoic acid is removed according to Eng. Pat. 22,787, 1891.

The para-toluene sulphonate of magnesium of the original operation is converted into toluene and acid magnesium sulphate by means of sulphuric acid and superheated steam. —J. W.

Acetophenonephenetidine. Preparation of. F. Valentiner, Leipzig-Plagewitz, Germany. Eng. Pat. 19,040, Oct. 10, 1895.

Acetophenone and paraphenetidine are heated in molecular proportions in a reflux distillation apparatus, with or without dehydrating agents. On cooling, acetophenonephenetidine crystallises out, and may be purified by recrystallisation from alcohol. It melts at 88° C., and is an antipyretic. —J. W.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photography in 1895. G. F. Jaulert. *Monit. Scient.* 1895, 46, 813—822.

For the preparation of "orthochromatic" plates, a number of new dyes have recently been suggested, and it has been found that the rhodamines possess several advantages over Erythrosin and Rose Bengal. Rhodamine 3 B [B] yields an emulsion, the maximum sensitiveness of which falls between the Fraunhofer lines D and E, extending halfway between D and C; while the hydrochloride or the ethyl ester of tetrachlorotetra-ethylrhodamine renders the plate sensitive almost up to the line C; all the rhodamine compounds giving better results in the blue than those of the first-mentioned dyestuffs. For the green portion of the spectrum, acridine yellow and orange are excellent, it being possible with the former to obtain all the lines from the orange into the violet: it should be useful, therefore, in taking negatives for the three-colour process. Alizarin blue S produces a film particularly sensitive between A and C, surpassing all other dyestuffs for the reproduction of the infra-red rays. The addition of a small quantity of silver nitrate to the usual ammoniacal solution of the blue, makes the plates even more rapid, but they will not keep.

For the avoidance of halation, Prestwich has devised an emulsion—bromide or citro-chloride—containing 1 to 2 parts of arrowroot to 3 of gelatin. Experiments on the influence of temperature on the rapidity of plates, show that between 0 and 30° C. there is little difference in speed, but beyond these limits considerable changes occur, an orthochromatic emulsion giving, at very low temperatures, a negative resembling one on an ordinary plate.

Phenylhydroxylamine (this Journal, 1895, 385) in 1 per cent. solution, mixed with 3 parts of sodium sulphite, makes a good developer, but addition of alkali is apt to cause fog. From recent work on the thiosulphates, it appears that the addition of free sulphurous acid to the ordinary fixing-bath should be avoided for fear of the production of sulphuretted hydrogen; but acid salts, such as bisulphites, may be advantageously employed. When using an acid fixing-bath after alkaline development, it is suggested to add a little aurin solution, as an indicator, to the "hypo," in order to show when the acid requires renewal. The addition of acetate of sodium or ammonium to the acid fixing bath to prevent the deposition of sulphur, and of common salt to hinder the decomposition of the silver thiosulphate, has also been recommended; a suitable formula being sodium acetate 3 parts, chloride 5 parts, thiosulphate 15 parts, water 200 parts. *Anthion* (potassium persulphate, this Journal, 1895, 298) in 0.5 per cent. solution, has proved a very efficient "hypo eliminator," surpassing the hypochlorites, as it has no action on the film; but, not being permanent when dissolved, it should be kept in the solid state.

A new "reducing"-agent for positives consists of an ordinary fixing-bath to which 0.2 per cent. of ammonium bichromate has been added. It is curious that "bromide" prints are not attacked by this solution, and in the case of chlorides produced by partial isolation followed by development, the bichromate, even if considerably strengthened, is only able to remove that amount of silver which has been deposited during the action of the light itself. This bath, accordingly, becomes a means of distinguishing between positives prepared by "printing-out" and development processes. A number of matt-surfaced gelatin papers are on the market at present, the dull surface being obtained by the addition of a little starch to the citro-chloride emulsion. To imitate platinum tones on these papers, it is advisable to expose them under the negative till they are of about half the required depth of tint, developing to the desired intensity with quinol (hydroquinone), washing very thoroughly, finally toning them in a bath made at least eight days beforehand. When toning the new colloidal-chloride papers by means of potassium platinoous chloride, the use of a 10 per cent. solution of acid sodium phosphate, mixed with an equal volume of 5 per cent. potassium oxalate, is recommended, to avoid any yellowing of the high lights. Experiments on metals other than silver have shown that many of the compounds of molybdenum, tungsten, and vanadium are more or less sensitive to light.

Further investigation of the diazo printing process (this Journal, 1895, 595), points to the compounds of α - and β -naphthylamine as the best to use; on development with sodium acetate the former yield a brownish-grey and the latter a reddish-brown print. The exposures required are about 2 to 3 minutes to direct sunlight, or 8 to 12 minutes to diffused light, and the process appears to work best on fabrics.

A new method of obtaining coloured photographs on silk has been worked out. It consists in producing on the material ordinary silver prints, after the manner of the albumin process. They are then finished in coloured pastels, the chalks being finally fixed by the action of a spray of caoutchouc dissolved in benzene.—F. H. L.

PATENTS.

Photographic "Process" Engraving, An Improved Method of Producing Negatives for. A. W. K. Bryan, Rochdale. Eng. Pat. 23,052, Nov. 28, 1894.

THE inventor claims, in the production of negatives for photographic "process" engraving, a special reticulated negative for the purpose of producing reticulations, by exposure, upon the surface of the photographic sensitised plate.—J. C. R.

Production of Prints by Photography, Improvements in. W. Friese-Greene, Chelsea. Eng. Pat. 1075, Jan. 16, 1895.

THE original specification and drawings must be consulted for details of the apparatus employed for "printing or reproducing, by means of photography, a number of copies from the same negative or negatives, by causing a band of sensitised material to travel intermittently through a chamber in which a negative or negatives are placed, and temporarily exposing a fresh section of the said sensitised band and the negative or negatives to the light in the said chamber after each intermittent movement of the sensitised band, the band being steadied during the exposure, whereby a photograph from the negative becomes reproduced upon the said section." Arrangements are also described whereby the sensitised material passes successively through two chambers, in the first of which it is printed on the one side, and in the second on the other.—W. M.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENTS.

An Improved Explosive for Producing Motive Power, and Apparatus to be used in connection therewith. T. Hawkins, Upton Park, London. Eng. Pat. 24,898, Dec. 21, 1894.

The improved explosive consists of a mixture of sodium nitrate, 6 parts by weight; sugar or syrup, 4 parts by weight; water, 36 parts by weight; potassium bichromate, 1 part by weight; potassium chlorate, 1 part by weight.

This mixture is converted into a fine spray in a special device described and illustrated in the specification, and introduced into an explosion-chamber forming part of the cylinder of the engine, or into a separate chamber serving as a pressure-generator, in either of which chambers it impinges against a heated metal plate kept hot by an external gas-flame or by electricity, when the explosive mixture is converted into gas, which, by valves, is allowed to act on a piston, as in an ordinary gas-engine.—W. M.

Igniferous Fuses, Improvements in the Manufacture of. J. Watson, London. Eng. Pat. 25,958, Dec. 24, 1894.

This invention relates to safety fuses made from a plastic mass containing nitrocellulose and nitroglycerin, with or without the addition of oxidisers, and the object is to diminish the sensitiveness to concussion, and liability to parting or breaking of the fuse core. The fuse core material is formed by pressing through dies, so as to leave a hollow central space; or the outer surface may have longitudinal grooves, so that when a textile covering has been spun around it, air channels will be covered in and be in direct communication with the fuse core. A textile cushion in the heart of the fuse core may be made by introducing some threads as the hollow core issues from the press. The central threads keep the fuse core from breaking, and the cushion of air outside or inside minimises the risk of accidents from concussion.—W. M.

Manufacture of Explosives (Perforation), Improvements in. H. Maxim, London. Eng. Pat. 16,861, Sept. 9, 1895.

The inventor prepares rods or strips of gelatinised explosives, with perforations parallel to each other, but at right angles to the longitudinal axis of the rod or strip.

—W. M.

Matches, An Improvement, or Improvements in, or connected with. J. I. Williams, Rnabon, North Wales. Eng. Pat. 18,575, Oct. 4, 1895.

The object of this invention is to enable ordinary matches, wood or wax, to be readily converted into fuses. For this purpose, collars or ferrules of the flaming composition, but without any fulminating composition, are prepared. One of these rings can be slipped up over the stem of the match until it jams on the head, the aperture in the collar being slightly conical, thus forming a fuse, or by removing the collar an ordinary match is available.

—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC CHEMISTRY.—QUALITATIVE.

Bromine and Iodine, the Halogen Derivatives of Sulphonamides as a New Reagent for. J. H. Kastle. Amer. Chem. J. 17, 1895, 704–708.

In the course of an investigation on the nature of the halogen derivatives of acid amides, the author prepared a number of di-halogen derivatives of the sulphonamides, two of which, the dibrom- and the dichlor-derivative of benzenesulphonamide, were found to be of exceptional beauty as regards crystalline character. It is shown that, as in the case of the halogen derivatives of benzamide, the amide itself is the final product of almost all the reactions. It is further shown that the dichloro-derivative of benzenesulphonamide decomposes metallic bro-

mides and iodides with formation of the metallic chlorides, and the corresponding bromo- and iodo-derivatives of the amide, and that when this decomposition is effected in the presence of carbon bisulphide or chloroform, the latter solvents are coloured yellow and violet, just as they are with bromine and iodine. On testing this new compound as a reagent for bromine and iodine, it was found possible to recognise 0.0000127 gm. of iodine in the presence of 0.04 gm. of bromine. The reagent is best prepared by dissolving benzenesulphonamide in the smallest possible quantity of caustic soda (1 in 10), and passing chlorine into the solution. A white precipitate is produced containing much unchanged amide. This is filtered off and the filtrate treated with more chlorine. The second precipitate consists chiefly, if not entirely, of the dichloro-derivative. It is filtered off and partly purified by heating with water and decanting. The dichloro-derivative, melting at 70°, and being nearly insoluble in hot water, is thus separated as a light yellow oil, which solidifies on cooling, and may be further purified by solution in alcohol and precipitation with water.—D. B.

Cobalt, Detection of, by the Nitroso-β-Naphthol Method. M. Hlinski. Chem. Zeit. 1895, 19, 1421.

The author combats the view that a mistake is likely to occur in the use of the nitroso-β-naphthol method for the detection of cobalt on account of the separation of small quantities of the reagent simulating the precipitation of the cobalt compound. The bright red colour of the cobalt precipitate is not to be confounded with the brown colour of the reagent. Figures are given showing that the method in question is more delicate, especially in the presence of nickel, than the reaction with potassium nitrite in acetic acid solution. The nitroso-β-naphthol reaction is best carried out by making the solution to be tested slightly acid with hydrochloric acid, then adding an equal volume of alcohol, and warming the mixture; fresh solution of nitroso-β-naphthol in 50 per cent. acetic acid is poured in, and the whole is brought to the boil. A voluminous purple-red precipitate of cobalti-nitroso-β-naphthol is produced, and can scarcely be confused with any other substance. When only a trace of cobalt is present, the cobalt compound remains in solution in the alcohol, and it is necessary to work with an aqueous solution. (Distilled water allowed to stand on nitroso-β-naphthol dissolves about 1 part in 5,000 in the cold.) The reagent should always be in excess, as a part of its function is to oxidise the cobalt to the cobaltic state. Even when only a colour is first produced, long standing will cause the separation of the characteristic red precipitate.—B. B.

INORGANIC CHEMISTRY.—
QUANTITATIVE.

Potassium Cyanate, Detection of Small Quantities in Potassium Cyanide. E. A. Schneider. Eng. and Mining J. 1895, 489.

By suitable modification of conditions, Blomstrand's colour reaction of potassium cyanate with cobalt acetate may be made very sensitive. The cyanide solution to be tested should be as strong as possible; it is decomposed, preferably in the German "Zehnkugelhöhren" (ten-bulb tubes), by means of a rapid stream of carbon dioxide, which is passed until all hydrocyanic acid has been expelled. Three grms. of KCy in a 10 per cent. solution may be thus decomposed in 45 minutes. To the residual liquid sufficient 95 per cent. alcohol (in some cases absolute alcohol) is added, to precipitate the potassium carbonate that has been formed. The carbonate is filtered off; the filtrate is slightly acidified with a few drops of acetic acid, and tested with cobalt acetate. The intense blue of the double cyanate of cobalt and potassium renders it possible thus to detect the presence of from 1 to 0.35 per cent. of potassium cyanate in the cyanide. If the quantity of cyanate be very small, a larger amount of the cyanide must be taken, which is dissolved in the smallest possible volume of water; the excess of cyanide is then precipitated out by means of absolute alcohol, and filtered; and the filtrate is treated with carbon dioxide, and tested as before.—W. G. M.

Zinc, Technical Analysis of. H. Nissenson and B. Neumann. *Chem. Zeit.* 1895, 1624—1626.

Of the various processes available, practically the only two which, for reasons quoted, are used in works' laboratories are Schaffner's sodium sulphide, and Galetti's potassium ferrocyanide volumetric methods. The latter is exclusively used in America, whilst the former, in a more or less modified form, is employed in Germany, Belgium, France, Spain, and Sardinia. In the Schaffner process, the titration is made in an ammoniacal solution, and the indicator may be ferric hydroxide suspended in the solution, or ferric chloride (Streng), nickel chloride (Kunzel), cobalt chloride (Deuss), alkaline lead tartrate (F. Mohr), lead acetate (Fresenius), sodium nitroprusside (C. Mohr), thallium nitrate (Schroder), or lead carbonate or "polka paper" (Schott) used by the drop method with paper. But of all these, only the first- (freshly precipitated ferric hydroxide) and the last-named are generally used. In the analysis of blende, 1 grm. of the ore (or 0.5 grm., if it contain more than 25 per cent. of zinc) is heated in a flask with 12 c.c. of strong hydrochloric acid, until all hydrogen sulphide has been driven off; the solution is then peroxidised with 3 c.c. of nitric acid, and after a short time 7 c.c. of (1:2) sulphuric acid are added, and the whole is evaporated until sulphuric acid fumes are observed. After cooling, the liquid is diluted and filtered. If cupriferosus, the solution is boiled before filtration with 5—7 c.c. of sodium thiosulphate solution (1:10) until no more smell of sulphur dioxide can be detected. The precipitate which contains the silica, lead, and copper is filtered off, and the filtrate is peroxidised with bromine water, and then treated with 25 c.c. of ammonia (sp. gr. 0.925) for the separation of iron, manganese, and alumina. After boiling and filtering, the precipitate is redissolved in hydrochloric acid (or in aqua regia, if highly manganiferous), and again precipitated. The mixed filtrates are made up to 500 c.c. and placed on one side for 12—18 hours for the removal of the great excess of ammonia. Simultaneously, a quantity of pure zinc, approximately equal to that in the ore under determination, is weighed accurately, dissolved in a similar quantity of hydrochloric and nitric acids, mixed with 25 c.c. of ammonia, and made up to 500 c.c. and placed also on one side. Coda has shown that, to insure accuracy, it is not necessary to employ sulphuric acid for the solution of the check zinc. A shorter method, employed by the authors, consists in taking double the quantities above quoted all through, dissolving and proceeding as above, but boiling with sulphuric acid only for 5 or 10 minutes (not to dryness) until red fumes cease to be evolved, making up to 500 c.c., after adding the ammonia, and filtering off only 250 c.c., which is then made up again to 500 c.c. for titration. The result may be a little low, but the error does not exceed 0.1 per cent., whilst the titration is better effected, owing to the absence of great excess of ammonia. The success of the whole process depends upon attention to details in the process of titration. The sodium sulphide solution should contain 35 grms. of the crystallised salt per litre, which is equivalent to about 0.01 grm. of Zn per c.c., but the titre rapidly alters on exposure to air, which necessitates the simultaneous performance of a check test with pure zinc. The burette may with advantage have a side-tube directly connected with the bottle containing the stock of standard solution, in order to minimise the action of the air when the burette is filled. Care must be taken that the colour of the spot upon the lead paper, which marks the end of the reaction, shall be identical in the ore- and check-solutions, as in that case the variation in the sensitiveness of the eyes of certain operators in regard to the detection of the first darkening of the paper, is eliminated. Two drops should be allowed to fall successively, after the lapse of a few seconds, upon the same spot upon the paper, the drops being taken from the solution by means of a narrow glass tube, which also serves as a stirrer. Towards the end of the operation, a test should be made after each fresh addition of 0.1 c.c., and very thorough stirring must be effected each time. A high temperature (even that of a hot summer's day) and a great excess of ammonia, alike interfere with the sharpness of the spotting reaction. The titration must, of course,

be made in a room of which the air is quite free from hydrogen sulphide. When copper is present it is possible to make a determination in the above way on a part of the solution, deducting from the result the equivalent of copper found colorimetrically in another portion; but this is not recommended, as the presence of copper sulphide interferes with the sharpness of the lead-paper indications. For approximate and rapid work with cupriferosus smelting products, the separation of copper may be avoided by adding to the ammoniacal solution, before titration, sufficient potassium cyanide solution to remove all but a trace of the blue colour from the liquid. A trace of blue is left to insure that no excess of cyanide shall have been added, as this would interfere with the accuracy of the result through the formation of a double cyanide of zinc. Results quoted show that volumetric tests, properly conducted, may give numbers in exact concordance with those obtained gravimetrically.—W. G. M.

Zinc, Volumetric Determination of, and a New Indicator for Ferrocyanide. G. C. Stone. *J. Amer. Chem. Soc.* 1895, 17, 473—477.

ALL the metals of the iron group, except manganese and zinc, having, if necessary, been removed from the solution containing the latter, the amount of manganese present is ascertained by titration with potassium permanganate, and then the zinc and manganese are determined together by precipitation with potassium ferrocyanide, using cobalt nitrate as an indicator.

The separation of iron and aluminium from the zinc and manganese is effected with barium carbonate, which should be freed from the alkaline hydroxide or carbonate, which it usually contains, by digestion with barium chloride.

After filtering off the precipitated aluminium and ferric hydroxides, the determination of the zinc and manganese should be proceeded with at once. If it should be necessary to allow the solution to stand, a little acid should be added to it, to prevent any zinc precipitating.

The manganese is estimated by boiling a portion of the solution, containing 0.1 to 0.4 per cent., and titrating with a solution of potassium permanganate containing 1.99 grms. per litre, 1 c.c. of this being equivalent to 0.001 grm. of Mn.

A second portion of the solution is rendered slightly acid with hydrochloric acid (addition of 5 c.c. of the concentrated acid per 100 c.c. of the solution prevents the precipitation of lead and causes no appreciable error; 10 c.c. prevent the precipitation of manganese) and titrated with potassium ferrocyanide. The solution of the latter is prepared by dissolving 30 grms. in a litre and is standardised by zinc or manganese in a slightly acid solution.

If much manganese be present, the colour of the precipitate becomes darker as the potassium ferrocyanide is added, and then, shortly before the end-point is reached, it suddenly changes to a pale green. It is unnecessary to commence testing with the cobalt nitrate until this change has taken place.

The test with the latter salt is made by placing a drop of a dilute solution on a porcelain plate and bringing a drop of the solution to be tested against it, so that the two touch but do not mix. An immediately shown, faint greenish line at the point of junction marks the end-reaction.

The manganese precipitate which is formed is not of normal composition, but consists of manganese and ferrocyanic acid in the ratio of $3\text{Mn} : 2\text{H}_4\text{FeC}_6\text{N}_6$.

A correction should be made for the amount of potassium ferrocyanide which is required to give a reaction with the cobalt nitrate. This is about 0.5 c.c. of a solution of the above strength per 100 c.c. of the solution to be tested.

—E. B.

PATENT.

Iron and Steel, A New or Improved Process for Determining the Carbonaceous Value of. G. W. Peipers, Remscheid, Germany. Eng. Pat. 662, Jan. 10, 1895.

THE improved process consists in comparing the marks made on unglazed porcelain by the piece of iron or steel to be tested, with those made by iron rods or pencils of known composition. The comparison is aided by partially

immersing the porcelain tablets in solutions which will dissolve the iron only, such as chloride of copper or of ammonium. After washing, the tablet may be treated with sulphuric or nitric acid, which will dissolve the carbon, leaving the graphite.—G. H. R.

ORGANIC CHEMISTRY.—QUALITATIVE.

Petroleum Benzine and Coal-Tar Benzene, Distinguishing between. Mitt. k. k. Versuchsanst. 1895, 13, [5], 241.

THE use of iodine has been recommended for the above purpose (Post, Chem. Techn. Analyse, 2nd Ed., 309; Böckmann, Chem. Tech. Unters. 985), the test depending on the variation in coloration of the solutions of iodine in the respective hydrocarbons and mixtures thereof. Attention is called to the conflicting statements of the above authors, and results of experiments are given in tabular form, showing that the test is of very limited value in regard to mixtures, visible variations of colour being determined only when the proportion of admixture is high.

Better results were obtained by taking advantage of the relative solubility of asphalt in benzene. The asphalt being prepared from Syrian asphalt by exhaustive washing with petroleum naphtha, to free it from constituents soluble in these hydrocarbons, was treated under uniform conditions with mixtures of petroleum benzine and coal-tar benzene, up to 70 per cent. of the latter. A well-graduated series of colorations from straw colour to dark brown, proportionate to the percentage of the latter, was observed. As an empirical test, therefore, it satisfactorily fulfils ordinary requirements.—C. F. C.

Naphthol Yellow in Vermicelli, Macaroni, &c., Detection of. F. Schaffer. Chem. Zeit. 1895, 19, 216.

FROM 10–20 grms. of the crumbled substance are warmed with about 40 c.c. of 50–60 per cent. alcohol. Addition of a few drops of pure hydrochloric acid to the solution of the colouring matter so obtained destroys the colour of naphthol yellow, but not of safranines, whilst Metanil yellow is coloured red. To identify the colouring matter with greater certainty, take 200 grms. of the substance and evaporate the alcoholic solution to a small volume. Hydrochloric acid then gives a whitish flocculent precipitate of dinitro α -naphthol, soluble in ether with a faint yellow colour. Naphthol yellow S is not precipitated by hydrochloric acid, but by soda, even in very dilute solution.—A. C. W.

Citric Acid, a Reaction of. Ludo Stahr. Nordisk pharm. Tidsskrift. 1895, 2, 141.

By the action of an oxidising agent on citric acid, acetone is formed; this by treatment with bromine, followed by an alkali, yields bromoform. To use these reactions as a test for citric acid, a few drops of deci-normal permanganate solution are warmed with 1 c.c. of the solution, and when the red colour has disappeared, 3–5 drops of saturated bromine water are added; on cooling, a white crystalline precipitate is obtained. If caustic soda be now added, the smell of bromoform is perceived. The test clearly indicates 2 mgrms. in 1 c.c. When bromine water is added first, a smaller quantity of permanganate is required for oxidation; thus bromine itself appears to act on citric acid. This is contrary to the results of Cloëz. If two equal quantities of bromine water, to one of which a little citric acid is added, be heated to expel free bromine, that portion to which the acid was added will be found to give a much larger precipitate of silver bromide than the other.—A. C. W.

Alkaloids and Glucosides, Characterisation of several.

E. Formánek. Rozprawy české akademie, 4, Cl. II., No. 9.

Alon.—The residue obtained on evaporation with nitric acid is coloured brown by ammonia and yellow by cold potassium hydrate solution. On evaporating with the latter, a deep violet residue is left, dissolving in water to a wine-red solution.

Amygdalin gives a colourless or pale yellow residue when evaporated with nitric acid, coloured rose by ammonia, and a transitory brown-rose with aqueous KHO. Alcoholic KHO gives a red-violet, changing to yellowish-brown.

Brucine.—Residue after evaporation with nitric acid, yellow, changing to grass-green (and subsequently to brown) with ammonia. Sulphuretted hydrogen water gives a violet, but KHO produces no characteristic coloration.

Strychnine.—Residue from evaporation with nitric acid is yellow, changed by ammonia to orange, and by KHO to red-violet, subsequently brown. This reaction occurs even when a large amount of brucine is present.

Ccotoin.—The solution in nitric acid is dirty green to brown, turning rose-red when heated. The brownish-red to brown residue is changed by aqueous KHO or ammonia to dirty green, then brown.

Paracotoin.—Forms red solution in sulphuric acid, changing to yellow. Residue after evaporation coloured red, and afterwards brownish-yellow, by aqueous KHO or ammonia.

Emodin.—Yellow solution in nitric acid. Evaporation residue brownish-vermilion, turning, with ammonia, to violet, and then to dirty red, and to violet, afterwards brown, with KHO.

Narcotine.—Nitric acid solution, dirty yellowish-green. Evaporated residue, yellow, changed to dirty green, then brown by ammonia, greenish-brown by KHO, passing into orange-brown, and turning a reddish-brown yellow on heating. Evaporated and strongly heated it becomes a bluish brick-red.

Physostigmine.—The yellow nitric acid solution leaves on evaporation a vermilion-red residue, turning to green after prolonged heating, and forming a green solution in water. KHO produces, after some time, a brown, as does also ammonia, but more slowly.

Salicin.—The pale yellow residue from evaporation of the nitric acid solution deepens on the addition of KHO or ammonia, and turns to a blood-red when heated with KCy on the water-bath.—C. S.

ORGANIC CHEMISTRY.—QUANTITATIVE.

Phenol and the Three Isomeric Cresols. G. Jørgensen. Chem. Zeit. Rep. 1895, 19, 190.

AN aqueous phenol after addition of soda is freed from water by distillation. Excess of dilute sulphuric acid is added to the residue; a second distillate then contains all the phenols. These may be extracted by ether and obtained crystalline by evaporation of the dry ethereal extract. The author considers that a determination of the iodine absorption of a phenol affords a more rapid and accurate estimate than is given by the weighing of tribromophenol or by the method of Koppeschaar, if other substances which absorb iodine are absent. As criteria of the purity of a phenol may be taken its iodine absorption and solubility (1 gram. of phenol absorbs 8.1 gram. of iodine).

The physical properties of these phenols are shown in the following table:—

	Phenol.	Ortho-Cresol.	Meta-Cresol.	Para-Cresol.
Melting point.....	42°	36°	3°	36°
Boiling point.....	182°	190°	202°	201°
Specific gravity....	1.0206	1.0578	1.0498	1.0522
Solubility (one part in parts of water).	15	19	200	55

—A. C. W.

Lard, Analysis of. A. Goske. Chem. Zeit. 1895, 19, 1043–1044.

THE recognition of tallow in lard by means of the test consisting of the observation of the behaviour of the substance when allowed to crystallise from ether, is best effected by conducting the test at a temperature of 12°–13° C., as a lower temperature causes a confused crystallisation. Under the microscope the crystals thus separated from pure steam lard have the form of sharp-edged plates, often as much as $\frac{1}{2}$ mm. in width. A few bundles of needle-shaped crystals of dark appearance are also scattered about the field. When tallow is present, needles disposed radially are predominant. In butcher's lard, on the other hand, needles

are commonly present in quantity, and can with difficulty be distinguished from those of tallow. The practice, occasionally adopted, of adding mutton tallow to lard increases the difficulty. The preparation and examination of samples by each observer must be adopted to ensure reliable results. Seeing that American steam lard appears to be softer (richer in olein) than the average European product, the author was led to suppose it possible that such difference was due to a difference of breed or food, but direct experiment with raw fat of American origin showed that the lard rendered therefrom in the laboratory differs in no essential respect from that from European sources. The cause of the difference in the commercial product known as steam lard is therefore unexplained. With regard to the detection of cotton-seed oil in lard, the author uses the Beechi test as directed by the Italian Commission, and in doubtful cases resorts to the expression of the more liquid portion of the fat at a temperature of 26° – 30° C. Comparison of the darkening of the more and less solid portions, gives useful indications.—B. B.

Oak-Wood Extract, Analysis of, by the Hide-Powder

Method. F. Čerych. Der Gerber. 1895, 21, 241–243.

THE most weighty source of error in the hide-powder method is the unequal quality of the powder: this is avoided if the powder be washed with cold water until the washings are no longer rendered turbid by a solution of tannin. Another error is, however, engendered by thus freeing the powder from soluble gelatin, for it is found that the filtrate which has passed through such purified powder contains tannin. This fact appears to be due to the passage of the liquid up the sides of the tube, where it does not come into actual contact with the hide-powder; the presence of soluble gelatin ensures the absorption of the tannin in this portion of liquid. To remedy this drawback to the method, the author mixes the hide-powder with disintegrated filter paper in order to increase its effective surface.

One hundred grms. of hide-powder from a trustworthy source, is washed as mentioned above and intimately mixed with a cream of 35 grms. of filter paper. The water in this mixture is wrung out in a linen cloth, and the material is powdered and dried by cold air. The dried powder is ground until it is in a woolly condition, and is dried over sulphuric acid until it contains about 1.5 per cent. of water. Of the finished material, 9 grms. serve for each determination. The water may be more rapidly removed by alcohol, and the powder thus dried can be preserved for a longer time, and is not deteriorated in absorbent power.

The passage of the tannin solution through the hide-filter should occupy 2–3 hours; if unduly prolonged, the non-tannin will generally be too high.

The following tables show the influence of the proportion of water in which an extract is dissolved, and of the temperature at which the analysis is made, on the results obtained:—

Extract dissolved in 1 Litre.	Total Solids.	Insoluble Matter.	Non-Tannin.	Tannin.
5 grms.	47.12	0.12	18.44	28.56
15 "	47.12	1.22	18.50	27.40
30 "	47.12	1.65	18.40	27.07

Thirty grms. of extract per litre:—

	16°	19°	25°	34°
Insoluble matter	1.65	1.18	0.22	0
Non-tannin	18.43	18.41	19.04	19.58
Tannin	27.04	27.53	27.86	27.54
Total solids	47.12	47.12	47.12	47.12

From the facts that the insoluble matter increases with the strength of the solution, decreases with increased temperature, and increases with decrease of tannin, it may be inferred that the "insoluble matter" is itself a sparingly soluble tannin. The increase of non-tannin with rise of

temperature shows that the hide-powder yields gelatin at the higher temperatures. The more dilute the solution of extract, the more marked are these discrepancies. Other tables in the original paper show that with unwashed hide-powder the non-tannin is somewhat lower than with the washed powder, and increases with increase of concentration; it is, however, only extracts that show this peculiarity (compare Koch, this Journal, 1891, 803).

The author concludes that in order to obtain concordant results by the hide-powder method, it is necessary (1) to purify the hide-powder in the manner indicated; (2) to use always the same weight of extract for analysis; (3) to work at the same temperature, best at 18° – 20° C., making sure that the solution has the same temperature when the insoluble matter is filtered and when the tannin is determined. The so-called insoluble matter is not without value, since it is now shown to be a sparingly soluble tannin.

—A. G. B.

Sugar, Volumetric Estimation of, by means of Ammoniacal Copper Solution. Z. Peska. Rozprawy České akademie, 1895, 5, Cl. II. [19].

INSTEAD of the usual current of hydrogen, the author now employs a layer of vaseline to prevent oxidation of the copper solution. Two solutions are prepared: the first consisting of 6.927 grms. of pure copper sulphate dissolved in 160 c.c. of 25 per cent. ammonia, and made up to 500 c.c.; the second, of 34.5 grms. of Rochelle salt and 10 grms. of sodium hydroxide dissolved in water and diluted to 500 c.c. A mixture of 50 c.c. of each of these solutions is heated to 80° under a layer of vaseline 5 mm. thick; the solution to be estimated is run in at the rate of 1 c.c. at a time for the first test, but on repetition the whole amount may be added at once. The temperature is raised to 85° , the heating continued for two minutes in the case of glucose and invert sugar, and for four and six minutes respectively in that of maltose and invert sugar. The solution is then titrated at the last-mentioned temperature until the colour just vanishes. Dextrin raises the reducing power of the sugar less in this solution than in one prepared with potash; moreover, the ammonia does not affect the accuracy of the results. One gm. of cane sugar is on an average equivalent to 0.0026 gm. of invert sugar. The sugar of milk is estimated after precipitation with lead acetate and sodium sulphate. The following table gives the number of milligrams of each sugar in 100 c.c. of solution:—

No. of Cc.'s of Sugar Solution used.	100 Cc.'s of the Sugar Solution contain Mgrms. of			
	Glucose.	Invert Sugar.	Milk Sugar.	Maltose.

Formic Acid, Determination of. F. Freyer. Chem. Zeit. 1895, 19, 1184—1185.

THE conventional methods of determining formic acid, *viz.*, that which consists in determining the quantity of mercurous chloride which is formed on boiling it with mercuric chloride, and that having the oxidation of the acid with permanganate as its basis, leave much to be desired. The author treats 10—20 c.c. of the formic acid solution, containing about 0.5 of the acid, with 50 c.c. of a 6 per cent. solution of potassium bichromate and 10 c.c. of strong sulphuric acid, boiling the mixture under a vertical condenser for $\frac{1}{2}$ to 1 hour. The solution is diluted to 200 c.c., and the unaltered chromic acid is determined by adding 1—2 grms. of potassium iodide, 10 c.c. of a 25 per cent. solution of phosphoric acid, allowing to stand for 5 minutes, and titrating back with $\frac{N}{10}$ thiosulphate solution. The addition of phosphoric acid is said to allow the change from blue to the green of the chromic salt to be more readily observed. The rubber stopper used to connect the flask with the condenser should be boiled out with bichromate solution, lest it exert a reducing action on the liquid in the flask. The method can be used in the presence of acetic acid. Test analyses are satisfactory.

—B. B.

Writing Inks, their Examination. G. Wisbar. Papier Zeit. 1895, 20, 3059.

A GOOD writing ink must answer all the following requirements:—It must be a true solution, permanent both in bottle and in ink-pot; it must not "skin"; it should not be too acid (the corrosive action on steel nibs, however, is due as much to the iron and the organic acids as to the

free mineral acid); it must not penetrate good paper, but after drying for eight days it should be sufficiently insoluble not to be obliterated by 24 hours' soaking in water or alcohol. It must not become mouldy, and should dry on the nib to a varnish-like film, not forming a crumbling powder. To examine any commercial sample, a standard ink must be prepared. 23.4 grms. of tannin and 7.7 grms. of crystallised gallic acid are dissolved in water at 50° C., 10 grms. of gum in solution, 2.5 grms. of hydrochloric acid, 30 grms. of ferrous sulphate (also dissolved), and 1 gm. of phenol added. The whole is made up to 1 litre, allowed to stand at least four days, and then decanted. 10 or 15 c.c. of the sample to be tested are removed from the bottle with a pipette without shaking, and the remainder well corked and set aside. It is then compared with the standard, and if the two differ in shade, the latter must be tinted to match the sample by the addition of 2 or 3 grms. per litre of one or more of the following dyes, as may be required:—Bavarian Blue D.S.F. [A.], Nakar Red S. [A.], Acid Green V.B.S.Po. [O.], and Chestnut Brown [O.].

A piece of good writing paper is then tightly stretched in a frame, constructed so as to cause part of it to slope at an angle of 45°, and provided with a support for a pipette (in order to insure its uniform position) from which 0.6 gm. of the ink is made to run gently down the slope, the pipette being ground to a similar angle at the base. Two or more stains of ink, one being the prepared standard, are thus obtained, and the paper is allowed to dry, exposed to light. The inks are then diluted with an equal volume of water, and fresh stains produced, the better to observe the darkening of the tint. When dry, all are put aside for eight days, in a place exposed to light and air, and then compared for colour, dustiness, and fluidity, the latter being judged by the shape of the marks on the paper. One portion is also soaked in water, another in 85 per cent., and a third in 50 per cent. alcohol for two days, then dried again at ordinary temperatures, to observe the solubility.

The presence of a sediment in the original bottles containing the ink samples is not necessarily a proof of want of permanence; it may simply be due to the ink having been bottled up before the proper time. The samples should be allowed to rest for three days, then 50 c.c. pipetted off from the middle of the liquid, filtered through a small paper, and 25 c.c. run into a small bottle, the neck of the funnel being kept below the surface of the filtrate. The bottle, which must always be of the same size and shape for this test, is lightly covered with paper, and observed for several days, a good sample remaining without sediment for a fortnight. The amount of iron may also be determined in the usual manner, and should not fall below that in the standard (0.6 per cent.). The above remarks apply equally well to the combined writing and copying inks, by which term are understood inks yielding two copies during the first 24 hours, and one on the following day.

A number of experiments have been tried by Schluttig and Neumann on the substitution of other substances for the tannic and gallic acids usually employed. They find that many phenols and their derivatives give strong colours when mixed with ferric salts, but that only those bodies which approach gallic acid in constitution—*i.e.*, possess three adjacent hydroxyl groups—are available for the manufacture of writing inks. They have also observed that the darker the original colour of the iron salt, the more permanent is the resulting ink, and that tannin is a much inferior substance to gallic acid to employ whenever any degree of permanence is required. Their researches also tend to throw doubt on the generally accepted view that tannin is a digallic acid: for, as such, it should possess five free hydroxyl groups, and should form, therefore, a darker and more permanent iron salt than gallic acid itself.

XXIV.—SCIENTIFIC AND TECHNICAL NOTES.

Petroleum Esters from the Spent Acids. Fuchs and Schiff. Chem. Zeit. 19, 1469—1470.

IN order to ascertain the practicability or otherwise of utilising for perfumery purposes the esters prepared by Zoloziecki and Aschan from the naphthene carboxylic acids contained in the residue from the alkali process in petroleum-refining, a sample of alkali sludge from an Austrian refinery was treated by Aschan's method, a pale yellow oil with a strong fatty-acid odour being obtained. This, although readily saponifiable with soda-lye, is unsuitable for soap-making, since the product breaks up rapidly when dissolved in water, and gives off the disagreeable odour of the fatty acids. By removing the hydrocarbons from this oil, and subjecting the residue to a series of fractional distillations from sulphuric acid, five fractions were obtained, from the acid numbers of which it was calculated that the mixture consisted of 66.78 per cent. of nononaphthene carboxylic acid and 33.22 per cent. of octonaphthene carboxylic acid. The ester prepared therefrom gave 92 per cent. of the theoretical yield, and had a pleasant odour, but proved unsuitable for use in perfumery by its behaviour when diluted, in which condition—contrary to the behaviour of the esters of the fatty acids—it lost its agreeable smell, and finally developed an odour resembling that of strong snuff. It may probably be found more suitable than eumarin for flavouring this substance. From a chemical point of view, the change signalled affords another proof of the constitutional difference between these acids and those of the fatty series.—C. S.

Shells of the Cocoa-Nut, Composition of. R. W. Tromp de Haas and B. Tollens. Annalen, 286, 303.

THE substance was finely powdered, and exhausted with dilute acid (HCl), and afterwards with ammonia, washed, dried, and exhausted with ether alcohol. The product thus purified was hydrolysed by boiling with dilute sulphuric acid (1 per cent. H₂SO₄). The solution, further treated in the usual way for the isolation of sugars, gave a satisfactory yield of crystallised xylose. The mother-liquors gave a further yield of the pentose, which appeared to be the only product of the hydrolysis.

The residue from the treatment was hydrolysed by treatment with strong sulphuric acid (Fleehsig, Zeits. Physiol. Chem. 7, 6), diluting, and boiling. From the solution crystallised dextrose was obtained.—C. F. C.

Oxycellulose. R. W. Tromp de Haas and B. Tollens. Annalen, 286, 296.

THE authors have further investigated the oxycellulose obtained by the action of nitric acid upon pine wood (*Ibid.* 267, 366; 271, 288). By solution in sulphuric acid (1.7 sp. gr.) and further hydrolysis, they have succeeded in obtaining dextrose. Treated with potassium hydrate solution at high temperatures (Lange), it yields a residue amounting to 20 per cent. of the original; the oxycellulose of Witz yields 50—60 per cent. of residue. On boiling with hydrochloric acid (1.06 sp. gr.), it yields furfural equal to 2.6 per cent. Previously dissolved in a mixture of sulphuric and hydrochloric acids, the yield was increased to 3.7 per cent., confirming the observations of Cross and Bevan (*Ber* 27, 1063). One of the authors (B. T.) follows the above communication with a few critical notes dealing with the observations of Cross and Bevan upon the furfural-yielding oxycelluloses (*Ber* 26, 2520; 27, 1061). These observations are confirmed. The products in question—the natural oxycelluloses—are “furfuroids” giving no pentose reactions. They may be oxy derivatives of the hexoses, probably similar in constitution to the glycosones, C₁₂H₁₆O₆ (*Ber* 22, 93), which are also easily condensed to furfural (Fischer).—C. F. C.

Sugars richer in Carbon, from Galactose. E. Fischer. Annalen, 1895, 288, 139—157.

THE author has built up from galactose, by methods already described (this Journal, 1890, 527, 638, 958, and

1141), oxy-acids, sugars, and alcohols containing one or more additional carbon atoms in the molecule.

The first addition of hydrocyanic acid to galactose results in the formation of two stereo-isomeric *gala-heptonic acids* (α - and β -acid).

α -Gala-heptonic acid lactone, C₁₂H₁₆O₇, already described by Maquenne and Kiliani (this Journal, 1889, 406), is crystalline when pure. Melting-point = 117° C. The lactone is very soluble in water, the solution being levorotatory, $[\alpha]_D^{25} = -52.2$, and forms a characteristic hydrazide, melting at 226° C.

α -Gala-heptose, formed by reduction of the preceding lactone, has not been obtained crystalline, but only in the form of a sweetish syrup. The sugar is feebly levogyrotary and is not fermentable. The hydrazone and osazone are crystalline, and melt at 205° and 224° C. respectively, with decomposition.

α -Gala-heptitol, obtained by further reduction of the heptose, crystallises in colourless needles melting at 187°—188° C. It is slightly sweet and rotates feebly to the left, $[\alpha]_D^{25} = -1.35$ ° (in borax solution).

Gala-octonic acid is the sole product of the further action of HCN on α -gala-heptose. Its lactone is crystalline, melts at 225°—228° C., and is only slightly soluble in cold water. The solution is dextro-rotatory, $[\alpha]_D^{25} = +64.0$ °. The hydrazide melts at 235° C.

Gala-octose, C₁₂H₁₆O₈ + H₂O, obtained by reduction of the preceding lactone, crystallises well in colourless, shining leaflets, melting at 109°—111° C. Its rotatory power exceeds +40°. The hydrazone and osazone melt at 205°—210° C. and 226°—231° C. respectively.

Gala-octitol, prepared from the octose, crystallises from alcohol in needles, from water in plates. It melts at 230°—232° C., is almost tasteless, and does not reduce Fehling's solution.

β -Gala-heptonic acid, produced in small amount, is separated with difficulty from the α -acid, and has not been obtained crystalline. It appears, however, to be feebly levorotatory, and furnishes a distinctive hydrazide, melting at 185° C. By treatment with pyridine and water at an elevated temperature the β -acid is converted partially into the α -compound.

β -Gala-heptose has been obtained crystalline. The sugar is sweet and melts at 195°—199° C. with decomposition. Its aqueous solution is levogyrotary, and when freshly prepared exhibits a strong biration. The deflection gradually increases, and becomes constant after about 24 hours, $[\alpha]_D^{25} = -22.5$ (after 10 minutes); -54.4 ° (after 24 hours).

The α - and β -gala-heptonic acids yield on oxidation with nitric acid, the corresponding gala-heptopentol-dicarboxylic acids, both of which are optically active (+). The α -acid was described by Kiliani (*loc. cit.*), and named by him *carboxy-galactonic acid*.—H. T. P.

New Books.

GAS MANUFACTURE, THE CHEMISTRY OF. A Practical Handbook on the Production, Purification, and Testing of Illuminating Gas, and the Assay of the By-Products of Gas Manufacture. For the Use of Students, Chemists, and Gas Engineers. By W. J. ATKINSON BUTTERFIELD, M.A., F.C.S. Chas. Griffin and Co., Limited, Exeter Street, Strand, London. 1896. Price 9s.

8vo volume, containing 333 pages of subject-matter, one page of bibliography, and the alphabetical index, 335—375. There are 62 wood engravings representing plant and analytical apparatus. In this work attention has been given to the recent extensive employment of petroleum for gas-making. The matter in the work is classified as follows:—I. Raw Materials of Gas Manufacture. II. and III. Coal-Gas. IV. Carburetted Water-Gas. V. Oil-Gas. VI. Enriching by Light Oils. VII. Final Details of the Manufacture of, and Sundry Schemes for Making and Enriching Gas. VIII. Gas Analysis. IX. Photometry. X. The Applications of Gas. XI. By-Products.

THE CHEMISTRY OF POTTERY. By KARL LANGENBECK, Chemist of the American Encaustic Tiling Co., &c. Chemical Publishing Co., Easton, Pa., U.S. America. 1895. Price 2 dols. Wm. F. Clay, Edinburgh.

THIS small 8vo volume opens with a preface, in which the author states that "whilst in the natural resources of a country the clays found on every side have seemed to offer a fruitful field for investigation, the information at command concerning the chemical needs of the potter has been so meagre that the efforts of our chemists have been practically abortive. The thousands of analyses published are mostly worthless, because they do not go far enough, or because unaccompanied by essential physical tests and practical trials." The hope expressed is that the present treatise will supply information that will turn future labours in this channel to good account. The book contains 191 pages of subject-matter, a frontispiece, and a few illustrations. The sub-divisions are as follows:—I. Analysis of Pottery Materials and Products. II. Physical and Empirical Tests. III. Pyrometry. IV. Classification of Ceramics. V. Pottery Glazes. VI. Red Ware. VII. Rockingham and Yellow Ware. VIII. Stoneware. IX. Raw Materials of White Ware Bodies. X. White Granite and Cream-coloured Ware. XI. Majolica and Enamelled Tile. XII. White Enamelled Brick. XIII. Floor-Tile and Terra-Cotta. XIV. Refractory Materials. XV. Burning the Ware. An alphabetical index of subject-matter is given.

L'INDUSTRIE DU BLANCHISSAGE ET LES BLANCHISSERIES. By ARTHUR BAILLY, Secretary of the Syndicate Chamber of Bleachers, Paris. Librairie J. P. Baillière et Fils, Rue Hautefeuille 19, Paris. 1896. Price, 5 fr.

THIS work is another of a series forming, as a whole, the "Encyclopédie de Chimie Industrielle." It is a small 8vo containing 376 pages of subject-matter. A preface at the beginning defines the extent and classification of the text as follows:—1. The Bleaching of New Pieces or Goods, of Yarns and Cottons. 2. Domestic Bleaching of Linen. 3. Industrial Bleaching (Cleaning), *i.e.*, such as carried on in establishments in or near to large towns. These branches are treated in the first part of the work, whilst at its close another but allied subject receives attention. The sub-divisions are as follows:—1. The Installation and Organisation of Public Wash-houses. 2. Special Bleach- and Wash-houses for the Linen of Hospitals, Restaurants, Hotels, and other Civil and Military Establishments. 3. System of Counting and Checking Linen, &c., received for Bleaching. 4. Relation between the direction of the above Establishments, their Personnel, and the ordinary business carried on. The work contains 106 illustrations, and the Table of Contents at the end serves as an index.

PROPOSED DUTY ON BOTTLES IN THE UNITED STATES.

See Board of Trade Journal, January 1896, 63.

GENERAL TRADE NOTES.

THE WOOD-PULP INDUSTRY OF CANADA.

Board of Trade Journal, January 1896, 40.

THE wood-pulp industry with a rapid growth has attained large proportions. By the census of 1891, the product of pulp-wood was 261,155 cords, but as it was then recorded for the first time there can be no comparison with the previous decades. Pulp-mills did not appear in the census of 1871; by that of 1881 the invested capital amounted to 92,000 dols., the wages to 15,720 dols., and the product to 63,300 dols.; by the census of 1891, the invested capital had increased to 2,900,307 dols., the wages to 292,099 dols., and the value of the product to 1,057,810 dols.

There has been a correspondingly large increase in the exports of wood for pulp. The article did not appear in the Customs returns of 1889. In 1890 its export was valued at 80,005 dols., in 1891 at 188,198 dols.; in 1892 at 219,548 dols.; in 1893 at 386,092 dols.; and in 1894 at 393,260 dols. The export of wood-pulp also made great strides, amounting in 1890 (its first appearance in the returns) to 168,180 dols.; in 1891 to 208,619 dols.; in 1892 to 355,303 dols.; in 1893 to 455,893 dols.; and in 1894 to 547,217 dols.

Three things are necessary to the successful development of the manufacture of pulp—suitable wood, extensive water power, and cheap labour. All the elements indispensable to the success of pulp manufacture are to be found in Canada, besides particular additional advantages. The immense forests of coniferous trees contain a practically inexhaustible supply of the different kinds of wood required in this line of manufacture. They are, moreover, of a superior quality and very much sought after by the manufacturers of the United States, as is seen in the yearly increasing demand. With regard to quality and quantity, Canada is as well situated as Norway and Sweden, if not better.

If the price obtained in England is taken as a criterion, Canadian wood produces better pulp than that of Norway and Sweden, for in 1893 Canadian pulp was sold in England at an average of 24·80 dols. a ton, as against 20·77 dols. for the Scandinavian product.

PAPER MILLS IN INDIA.

Board of Trade Journal, January 1896, 86.

According to information received from the India Office, there are ten paper mills—four in the Bombay presidency,

four in Bengal, one at Lucknow, and one at Gwalior, which was worked for a short time only in the past year and then closed. Of the ten, three are private concerns in the Bombay presidency, one of which has not been at work for many years. The others have an aggregate nominal capital of Rs. 612,200. The fibrous materials used for making paper are chiefly rags, babai and moonj grasses, straw, jute, and hemp cuttings, and old jute bags and cloth. The quality of the papers made is now very good, and they have a large and increasing sale. Most of the white and blue foolscap and much of the blotting paper, note-paper, and envelopes used in the Government offices is now obtained from the Indian mills. The total quantity of paper made in 1894 was about 34½ million lb.; ten years previously it was about 13 million lb. The value of the out-turn in 1894 is reported at over Rs. 500,000. The number of persons employed is 3,544.

PRODUCTION OF SUGAR IN GERMANY.

Board of Trade Journal, January 1896, 78.

According to the German official statistics as to the production and taxation of sugar in the German Customs district, there were in operation in 1894-95 467 sugar manufacturing, 405 of which were beet-root sugar factories, 56 were sugar refineries, and 6 were for extracting sugar from molasses. These factories, according to *Handel's Museum*, used altogether 14,521,030 tons (metric tons of 2,204 lb.) of

beets, and produced 1,692,011 tons of raw sugar, as well as 992,136 tons of sugar of all kinds ready for consumption, the figures for the 1893-94 campaign being 1,270,508 tons of raw sugar and 819,639 tons of sugar ready for consumption. The quantity of beet-roots worked up was the largest ever known in Germany; the 1893-94 figures were 10,544,352 tons. The importation of sugar into Germany was insignificant, and remained at about the same level as in the previous year. On the other hand, considerably larger quantities of sugar were exported in 1894-95 than in the previous year, although the export of molasses has fallen off. In 1894-95, 609,663 tons of raw sugar and 392,857 tons of sugar ready for consumption were exported, as compared with 136,674 tons and 262,610 tons respectively in 1893-94. The consumption of sugar in Germany in the year 1894-95 was computed at 552,695 tons of refined sugar, i.e., 10·7 kilos. (23½ lb.) per head of the population, which compares with 10·1 kilos. in 1893-94 and 9·1 kilos., the average of the last nine working years.

UNITED STATES MINERAL PRODUCTION IN 1895.

Engineering and Mining Journal, January 4th, 1896, 1.

The value of the metals produced from domestic ores in the United States in 1895 amounted to 240,997,020 dols., as compared with 194,095,622 dols., the value of the output of the same metals in 1894. This is an increase of 24·2 per cent.

Metal Production of the United States in 1894 and 1895.

The value of the coal output increased 16·6 per cent., or 27,278,129 dols., and of iron ore 112·1 per cent., or 16,650,000 dols.

UNITED STATES CHEMICAL IMPORTS.

Engineering and Mining Journal, January 4th, 1896, 20.

The imports of heavy chemicals into the United States for the 10 months ending October 31st, according to the Bureau of Statistics, were as follows:—

Soda ash, 229,349,774 lbs. in 1895, against 229,081,101 lbs. in 1894; bleaching powder, 86,511,857 lbs. in 1895, against 78,529,773 lbs. in 1894; caustic soda, 54,705,758 lbs. in 1895, against 36,483,160 lbs. in 1894; sal soda, 5,792,659 lbs. in 1895, against 18,928,704 lbs. in 1894; other salts of soda (excepting nitrate), 1895, 8,060,760 lbs., and 1894, 14,645,153 lbs.; chlorate of potash, 4,028,191 lbs. in 1895, against 3,768,837 lbs. in 1894.

SODA PRODUCTION IN THE UNITED STATES.

Engineering and Mining Journal, January 4th, 1896, 20.

The production of soda in the United States is increasing rapidly, and the output for the year 1895 was about

161,000 metric tons, counted as 58 per cent. ash. (It is a satisfaction to have one industry in which the greater part of the product is counted in metric tons.)

The great Solvay Works are preparing to increase capacity by 50 per cent. through their new Detroit Works. The Mathieson Alkali Company at Saltville, Va., is also preparing to make a large output of ash and caustic during the coming year, and is now working the Castner electrolytic process with excellent results. This Company has a magnificent plant, and will no doubt become a very important factor in the market.

The neighbourhood of Detroit, Mich., will shortly become a great, if not the greatest, alkali producing centre in the United States. The new Solvay works, now under construction, the Michigan Alkali Works at Wyandotte, Church and Co. at Trenton, and two other projected works, are all in the vicinity of Detroit. The Standard Oil Company is also proposing to operate alkali works at Cleveland, O., and there are two or three other projected works in other parts of the country.

THE PRODUCTION OF GLUCOSE IN GERMANY FROM AUGUST 1ST, 1894, TO JULY 31ST, 1895.

Floorcloth..... Sq. Yds.	20,185,700	22,434,800	752,415	863,057
Painters' materials Val. £	1,374,034	1,553,878
Paper..... Cwt.	901,680	906,809	1,412,649	1,437,857
Rags..... Tons	53,834	49,353	309,684	294,473
Soap..... Cwt.	576,537	730,152	621,292	756,924
Total value	28,120,801	31,493,137

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

23,665A. L. Mond. Apparatus for treating solid and pasty substances with gases at elevated temperatures. January 14. Date claimed December 10, 1895.

24,697. W. R. Herriog and M. Graham. Improvements in apparatus for charging inclined gas retorts. Complete Specification. December 16.

24,104. F. D'Arcy McNally. Improvements in hydrometers, saccharometers, and other like instruments. December 16.

24,138. C. A. Rittel and J. Hodgson. Improvements in the manufacture of vessels of aluminium or alloys of the same for cooking, heating, boiling, evaporating, and other purposes. December 17.

24,214. E. Powell. Improvements in furnaces. Complete Specification. December 17.

24,311. D. Allan. An improvement in air, gas, and liquid tight couplings for metal, rubber, vulcanite, or other tubing. December 19.

21,337. L. A. Chevalet and W. Bobby. Improvements in apparatus for heating and purifying water. December 19.

24,499. G. P. Wallis. Improvements in hydraulic presses for expressing oil from seeds and such like. December 21.

24,508. H. Eckardt. Improvements in and connected with regenerators for furnaces. December 21.

24,709. J. L. A. Aymard. Improvements in sterilising apparatus. December 24.

24,835. W. Raydt. Improvements in apparatus for filtering liquids and impregnating the same with gases. December 27.

24,890. W. Hainsworth. An improvement in ladles for molten metal. December 28.

24,943. T. B. Jones. Improvements in or connected with apparatus for filtering sewage and other liquids. December 30.

25,949. D. A. Peniakoff. Improvements in rotatory apparatus for calcining substances. December 31.

1896.

75. W. W. R. Warn and L. F. King. Improvements in or connected with calcium carbide gas generators. January 1.

282. R. H. Courtenay. Improvements in lamps for the combustion of special chemical compounds, with means for condensing the burnt products of combustion. January 4.

424. G. E. Sherwin. Appliances for cooling and heating air and liquids. January 7.

469. J. U. Askham. Improvements in apparatus for separating substances of different sizes or specific gravities. Complete Specification. January 7.

889. F. Godard. Improvements in apparatus for refrigerating liquids. January 13.

947. C. E. Mumford. Improvements in apparatus for turning malt and like materials on a kiln floor. January 14.

1112. D. A. Quiggin. Improvements in and relating to evaporators, condensers, and the like. January 16.

1177. C. S. Meacham. A new or improved apparatus for separating bodies of different specific gravity when immersed in a liquid. January 17.

1228. D. M. Hawes. See Class XI.

1294. C. B. Inman. A carbonating machine. January 18.

1300. C. Polony. See Class II.

COMPLETE SPECIFICATIONS ACCEPTED.*

1895.

2723. F. H. Eydman. Apparatus for heating, evaporating, distilling, and condensing. December 26.

2824. S. M. Lillie. Apparatus for the continuous concentration of liquids. December 31.

3118. J. Foster. Evaporating apparatus. January 15.

4282. B. J. Green and W. Oates. See Class II.

4792. J. E. Carroll. Boiler feed-water heating and purifying apparatus. January 22.

18,518. S. Pitt. From La Société Internationale des Procédés A. Seigle. Apparatus for treating liquids by means of heat. January 15.

23,989. W. R. Herring and M. Graham. Apparatus for charging inclined retorts. January 22.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS

24,688. W. Synncock and G. Gosling. An apparatus for the production and automatic distribution of acetylene gas. December 16.

24,107. F. Horridge. Improved apparatus for heating purposes. December 16.

24,196. E. B. Pym and J. Gore. Improvements in apparatus for use in the manufacture of acetylene gas. December 17.

24,289. C. J. Yarnold. Improvements in or relating to the manufacture of ozone, and apparatus therefor. December 18.

24,302. A. Guillemaire. Process for deodorising and colouring in gold-yellow colour of oil and essence of petroleum and their derivatives. December 18.

24,381. L. Denayrouze. Improvements in the method of and apparatus for charging air with combustible matter and applying it for illuminating. December 19.

24,384. S. Cutler. An improved oil atomiser for gas carburetters. December 19.

24,505. A. Taylor and W. S. Taylor. Improvements in methods for incandescent gas lighting. December 21.

24,566. T. Holliday and J. H. Exley. Improvements in apparatus for manufacturing acetylene gas. December 24.

25,783. J. H. Paul. Improved treatment of spent oxide. December 27.

24,810. J. Moeller. An improvement in apparatus for making oil gas. December 27.

24,864. S. Learoyd. Improvements in fire-lighters by the coating of coal and other fuel. December 28.

25,000. S. Bender and T. Micoch. Improvements in furnaces and in the combustion of fuel. December 31.

1896.

148. W. G. Potter. Improvements in the manufacture of incandescent mantles for gas or oil lamps. January 3.

155. C. M. Stead and J. E. Brooke. An improved method of and means for enriching and burning lighting gas, and apparatus therefor. January 3.

317. G. Love. Improved apparatus applicable to coke ovens. January 6.

322. J. C. Bayley. An improved apparatus for generating, storing, and purifying acetylene and like gases. January 6.

361. H. Bower. Improvements in methods of separating the cyanogen compounds from gas liquor or other solutions containing cyanogen compounds. January 6.

395. A. Garton. Improvements in automatic apparatus for the manufacture of acetylene gas. January 7.

558. J. H. H. Duncan. Improvements in the production of incandescent mantles or bodies for gas and vapour lamps. January 8.

682. H. C. B. Forester. Improvements in and in the manufacture of artificial fuel. January 10.

771. M. Seipp. Process and apparatus for the complete combustion of coal-dust of different-sized particles in coal-dust or gas furnaces that may be immediately stopped. Complete Specification. January 11.

841. G. W. Breffit and F. G. Treharne. A new furnace for producing coke, with or without suitable apparatus for collecting the by-products. January 13.

858. A. Davis. Improvements in the process of and apparatus for carburetting air. January 13.

873. W. Raydt. Improvements in means for obtaining carbonic acid from gaseous mixtures. January 13.

1116. F. Rosbach-Rousset. An improved process and apparatus for the production of acetylene gas for acetylene gas lighting. Complete Specification. January 16.

1129. F. Knecherl. An improved method of producing light. January 16.

1136. F. Kollm. Incandescent body for illuminating purposes. Complete Specification. January 16.

1390. C. Polony. A process and furnace installation for continuous process of production of a non-exploding mechanical admixture of oxygen and hydrogen. January 18.

1332. C. G. Lu's. Improvements in apparatus for use in the production of acetylene gas. January 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

1067. T. Rowan. Apparatus appertaining to gas lighting. January 15.

1953. L. M. Bullier. Carburetting air and gases. January 22.

4282. J. J. Green and W. Oates. Retorts for the manufacture of gas and for other purposes. December 26.

4750. W. Ure and S. T. Crossdell. Constructing and working coke ovens for the manufacture of metallurgical coke. January 22.

4879. G. Hayeraft. Manufacture of artificial fuel. January 22.

11,848. H. H. Lake.—From E. N. Dickerson. Processes and apparatus for the production of combustible gas. December 26.

11,848a. H. H. Lake.—From E. N. Dickerson. Method and apparatus for supplying combustible gas for illuminating purposes. December 31.

12,215. A. Sweetser. Production of oxygen gas and apparatus therefor. January 15.

15,168. W. Foulis and P. F. Holmes. Apparatus for obtaining cyanides from gases. January 8.

19,916. W. Ewing and J. Meikle. Apparatus for enriching illuminating gas. January 8.

21,927. N. Baron. Method of increasing the lighting power of petroleum. December 26.

23,057. G. Seeligmann. Lighting material and apparatus. January 22.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

24,080. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Improvements in the manufacture of colour lakes. December 16.

24,184. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture of azo dyestuffs. December 17.

24,193. G. B. Ellis.—From La Société Chimique des Usines du Rhône, anct. Gilliard, P. Monnet, and Cartier. Improvements in the production of para-nitro-phenol and ortho-nitro-toluene-para-sulphonic acid. December 17.

24,194. G. B. Ellis.—From La Société Chimique des Usines du Rhône, anct. Gilliard, P. Monnet, and Cartier. Improvements in the production of para-nitro-phenol and ortho-nitro-toluene-para-sulphonic acid. December 17.

24,195. J. C. Mewburn.—From F. von Heyden Nachfolger. Improvements in the manufacture of para-amido-benzoic-sulphinide and of certain amides. December 17.

24,779. I. Levinstein, and Levinstein, Lim. Improvements in the manufacture of colouring matters. December 27.

24,842. C. D. Abel.—From L. Durand, Huguenin, and Co. Manufacture of new nitrated oxazine colouring matters dyeing with mordants. Complete Specification. December 27.

1896.

658. O. Imray. — From The Society of Chemical Industry in Basle, Switzerland. Manufacture of colouring matters dyeing wool green-black to blue-black. Complete Specification. January 10.

890. G. W. Johnson.—From Kalle and Co. Improvements in the manufacture of dry diazo compounds. January 13.

1331. H. H. Lake. — From K. Oehler. Improvements in the manufacture of colouring matters. January 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

3488. S. Pitt.—From L. Cassella and Co. Manufacture of blue safranin-azo dyestuffs. December 26.

3497. H. E. Newton.—From The Farbenfabriken vormals F. Bayer. The manufacture or production of naphtho-fluoresceine. December 26.

3580. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of a new dihydroxynaphthalene, and of certain sulphonic acids derived from this dihydroxynaphthalene or from the corresponding amidohydroxynaphthalene. December 22.

4018. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of direct-dyeing colouring matters. December 26.

4448. A. G. Green and R. Jansen. The manufacture and production of a new anilino base and of colouring matters therefrom. December 31.

4880. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of dyestuffs. January 15.

4961. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of derivatives of hydroxy-anthraquinone. January 15.

4962. H. E. Newton.—From The Farbenfabriken vormals F. Bayer. The manufacture or production of α - β -dihydroxynaphthalene, a new α - β -dihydroxynaphthalene sulphonic acid, and of colouring matters derived from α - β -dihydroxynaphthalene sulphonic acids. January 15.

5042. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of new basic azine dyestuffs and of new derivatives thereof. January 15.

5153. A. Bang.—From G. A. Dahl. Mordant-dyeing dyestuffs. January 15.

22,482. O. Murray.—From The Society of Chemical Industry in Basle. Manufacture of orange colouring matters by electro-chemical process. January 22.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

24,317. G. Douglas. Improvements in certain textile fabrics. December 19.

24,493. J. Fulton. Improvements in and relating to the weaving of textile web fabrics. December 21.

24,497. J. H. MacMillan and J. Mason. Improvements in the manufacture of crimped or mercerised woven fabrics. December 21.

24,586. L. Schniewind and A. Schmidt. Improvements in elastic woven textile fabrics. Complete Specification. December 23.

24,643. J. Y. Johnson.—From S. Wallach and Co., and E. Schweitzer. An improved process for removing mineral oil stains from vegetable fabrics. December 23.

24,696. J. MacDonald. Improved apparatus for decortiating reed grass and similar fibrous plants. December 24.

24,787. G. E. Wright and W. Monk. Improvements in the process of and material employed for degreasing and recovering oil and grease from wool, cotton waste, and other fibrous materials. December 27.

1896.

240. G. E. Wright and W. Monk. Improvements in apparatus for degreasing, scouring, and washing wool, cotton waste, and other fibrous materials. January 4.

340. G. Smith. Improvements in lining cloths or fabrics known as "fibre chamois," "fibre ramie," "fibre," or "fibrine." January 6.

492. J. Baxter, G. A. Baxter, and W. H. Hare. Improvements in finishing woollen or worsted fabrics. January 8.

877. J. J. Manu. Improvements in the manufacture of impermeable fabrics. January 13.

908. J. H. Macmillan and J. Mason. Improvements in the treatment and manufacture of textile fabrics. January 14.

1104. J. L. Bottomley. An improved manufacture of yarn. January 16.

1208. S. Schwabe and Co., Limited, and A. Binz. Improvements in the treatment of textile fabrics, to produce crinkled effects. January 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

1518. F. Girard. Waterproofing paper and other fabrics and apparatus therefor, and in means for applying waterproof designs thereto. January 15.

2711. R. Aitken. Treatment of animal fibres and mixed animal and vegetable fibres. January 15.

3041. K. T. Sutherland and G. Esdaile. An improved method of degumming or separating the filaments of stalk fibres. January 15.

3590. E. Lashbordes. A process for chemically cleansing wool and woollen fabrics and rags. December 26.

22,817. C. Wetherwax. Method and apparatus for removing gummy and other matters from vegetable fibres. December 31.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

24,392. M. Beraud and A. Lautmann. Improvements in dyeing wool, silk, and the like. December 19.

24,789. S. Schwabe and Co., Lim., and J. Gilbertson. Improvements in the process of and machinery for printing woven fabrics. December 27.

1896.

372. A. M. Clark. From C. H. Boehringer. Improvements in the process of mordanting vegetable textile materials for dyeing. January 6.

1048. W. P. Thompson. From E. Dambremé. Improvements in mechanism for dye vats. January 15.

1290. J. Stalker and C. C. Connor. Improvements in the fixing or fastening of colouring matters on fibre, yarns, and fabrics in such manner as to resist the action of soap, alkalis, and light. January 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

1691. G. Markus, M. Baender, and F. Sicker. Improvements in or relating to processes and apparatus for printing yarns in skeins. January 15.

3905. L. Rivett and R. H. Scott. Printing calico and other woven fabrics of cotton and cotton warps. January 22.

4671. J. G. Haslam. Dyeing apparatus. January 15.

23,592. S. Pitt.—From L. Cassella and Co. Process for rendering wool dyeings fast to "potting" or "spungeing." January 15.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

24,122. J. Enright. Improvements in the manufacture of sulphur dioxide and its derivatives, and apparatus therefor. December 17.

24,171. J. H. Darby. Improvements in the manufacture of ammonium salts. December 17.

24,848. H. H. Lake.—From O. O. B. Froelich. Improvements relating to the preparation of compounds of fluoride of antimony. December 27.

24,920. A. McDougall. The treatment of organic matters containing nitrogen for the production of ammonia and residual products. December 30.

1896.

75. W. W. R. Warn and L. E. King. See Class I.

335. H. R. Angel. Improvements in the manufacture of caustic soda, carbonate of soda, and sulphide of sodium. January 6.

579. J. B. Hilliard. Improved process of manufacturing chlorine gas. January 9.

720. B. Willecox.—From The Chemische Fabrik Griesheim. A process for obtaining hydro-sulphide of sodium or sulphate of sodium and sulphuretted hydrogen and sulphate of calcium from sulphide of calcium or soda residues and mono- or bi-sodium sulphate. January 10.

928. J. Foster. Improvements in and relating to the discharging of salts and the like from evaporators. January 14.

1022. A. von Rad and J. Rosenfels. Improvements in the manufacture or production of cyanogen compounds. Complete Specification. January 15.

1275. W. Mills. Improvements in manufacturing the silicofluoride of ammonium. January 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1894.

18,526. J. Hargreaves and T. Bird. Manufacture of chlorates of sodium and potassium. January 8.

1895.

1168. U. F. Benker. Manufacture of sulphuric acid. January 22.

2660. A. E. Morgans. Production of cyanogen compounds. January 22.

2820. L. M. Bullier. Process for the manufacture of carbides or acetylides of the earth metals and alkali earth metals and of the oxides or salts of these metals. January 22.

3489. T. H. Bell.—From T. Schloesing. Manufacture of chlorine by means of magnesium chloride. January 22.

4267. J. Y. Johnson.—From The Verein Chemische Fabrik. Manufacture or production of chlorine. December 31.

5662. C. Hoepfner. Production of zinc chlorides. January 22.

7171. H. Reichardt and J. Bueb. See Class XVI.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

21,263. J. Badon. A new product for use in substitution of sheet glass for windows, engraved glass, painted glass, blinds, curtains, and other purposes. Complete Specification. Filed December 18. Date applied for June 14, 1895, being date of application in Belgium.

21,267. W. Schreiber. Process for durably burning aluminium ornaments into porcelain, stoneware, majolica, glass, and stove tiles, as also enamelled iron utensils. December 18.

24,283. F. Albrecht.—From W. Knapp. Improvements in or appertaining to the process for the production of coloured pictures, writing, or the like on glass, porcelain, enamel, or sheet iron. December 18.

24,286. A. J. Boulton.—From La Société Anonyme Belge pour la Fabrik des Emaux Artistiques. An improved manufacture of glass. December 18.

24,313. F. F. Warren. An improved apparatus for blowing glass bottles, sheet glass, and glass in every shape, which I call the "Warren system." December 19.

24,314. F. F. Warren. An improved apparatus for blowing glass bottles, sheet glass, and glass in every shape. December 19.

24,379. O. Lauch. Improvements relating to the ornamentation of majolica tiles, vases, and the like. December 19.

24,596. R. Thorburn. Improvements in or connected with the manufacture of tiles or other similar articles. December 23.

24,858. J. Maddock. A kiln hook for placing pottery-ware during fire. December 28.

24,907. J. Phillips. See Class IX.

24,933. H. A. Rumbelow, G. Rumbelow, H. St. R. Rumbelow, E. Rumbelow, K. Rumbelow, M. St. R.

Rumbelow, and G. Hall. Improvements in dead or glazed faced white and coloured bricks and building blocks, roofing and ornamental and fire tiles, sanitary pipes and ware, paving stones and pottery. December 30.

1896.

46. A. Kopp's Sohn. Improvements in the manufacture of articles of glass. January 1.

177. The Worcester Royal Porcelain Co., Lim., and E. P. Evans and C. F. Bions. Improvements in the manufacture of plates and other similar articles of pottery or earthenware. January 3.

251. D. Moore. Improved leer or lehr for annealing glass. January 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

1221. W. Smith. An improvement in or pertaining to the "salt-glazing" of earthenware, stoneware, and other brittle articles. November 27.

1645. J. A. Fleming and E. Woollam. A rectangular oven or kiln for firing clay goods in any stage of manufacture, or other materials. December 31.

2175. A. Sherwin and C. W. Cobden. A novel or improved compound for use in the process of decorating or ornamenting ceramic ware. December 26.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

24,674. F. B. Bond. Improved fireproof flooring roofing, beams, brusses, and the like. Complete Specification. December 24.

24,898. M. Nahsen. An improved process for the manufacture of cement and cement-mortar. Complete Specification. December 28.

24,907. J. Phillips. Improvements in continuous kilns for burning bricks, tiles, terra-cotta, lime, &c. December 28.

24,967. M. Hoeft. Improvements in the production of marble-like stucco or plaster-work suitable for walls, ceilings, and the like. December 30.

1896.

68. W. R. Taylor. Improvements in apparatus for burning cement-making materials, lime, chalk, and the like, and the obtainment therefrom of carbonic acid gas. January 1.

643. A. W. Perriman and W. Owen. Improvements in or relating to the manufacture of steps, building or monumental slabs, and other articles of artificial stone, asphalt, or the like, and apparatus therefor. Complete Specification. January 9.

759. G. R. Hislop. Improvements in apparatus for revivifying spent limes, and for calcining cements and ores, or like materials. January 11.

1145. H. H. Lake. From A. D. Tyler, jun. An improved process for impregnating wood, or articles composed of wood, with solid or semi-solid substances. January 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

2710. R. Aitken. Treatment of wood with a view to preserving and colouring the same. January 15.

3608. F. Young. Manufacture of fire-clay refractory and non-conducting bricks and blocks, building bricks, or the like. December 26.

8402. G. R. Dawney. Improved tiles for permanent mentering, to be used in the construction of fireproof floors. January 8.

18,189. G. Michaelson. A process for imparting shaded colouring to, and for speckling or "curling" wood and the like. December 26.

22,201. B. Lohr. Process for producing compound asphalt and concrete slabs or plates, or compound plates or slabs of two similar substances. January 15.

23,145. E. H. Hurry and H. J. Seaman. New or improved process and apparatus for the manufacture of Portland cement and other similar cement. January 22.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

24,127. T. M. Ash and H. N. Weldon. An improved process for coating or plating non-metallic articles with metals. December 17.

24,241. J. H. Richards. A protective covering or coating for metallic wire and the like. December 18.

24,246. R. Thomson, J. Addie, and R. Addie. Improvements in treating auriferous, argentiferous, or other metalliferous ores for the extraction of the metals, and in apparatus therefor. December 18.

24,247. J. Addie, R. Thomson, and R. Addie. Improved process of treating auriferous, argentiferous, or other metalliferous ores to facilitate their separation from solvents used in extracting the metals therefrom. December 18.

24,248. J. Addie, R. Thomson, and R. Addie. Improvements in treating auriferous, argentiferous, and other metalliferous ores for the extraction of the metals and for the separation and recovery of the solvent employed in such treatment, and in apparatus therefor. December 18.

24,703. R. Heathfield and W. S. Rawson. An improvement in galvanising. December 24.

24,803. L. Pelatan and F. Clerici. Improvements in means or apparatus for the obtaining of precious metals from ores or materials containing them. Complete Specification. December 27.

25,095. W. J. Studds. Improvements in the methods of obtaining gold from antimony or ores or compounds containing antimony. December 31.

1896.

40. S. Callow. Silver alloy. January 1.

123. J. Giers. Improvements in furnaces for the manufacture of cast steel and homogeneous iron. January 2.

128. H. F. Julian. Improvements in the process of extracting metals from solutions. January 2.

202. E. Placet. Improvements relating to the treatment of metals, and to products resulting therefrom. January 3.

203. E. Placet. Improvements in the treatment of iron and steel. January 3.

244. F. T. Franke. Improvements in and connected with annealing or tempering furnaces. Complete Specification. January 4.

303. C. C. Longridge and G. T. Holloway. Improvements in plant and process for smelting auriferous antimony ores. January 4.

315. W. H. Bennett. Process for soft-soldering aluminium. January 6.

549. W. Blackmore. The treatment of antimonial and arsenical ores, materials, or furnace products containing gold, silver, or platinum. January 8.

618. J. B. Torres. Improvements in or relating to the extraction of metals from their ores and other metal-containing compounds, and in apparatus therefor. January 9.

1055. A. J. Boulton. From C. Prioux and C. Hugot. Improvements in or relating to soldering metals. January 15.

1096. T. Hampton. Improvements in the manufacture of steel. January 16.

1146. L. Doig.—From Russel and Erwin Manufacturing Company. An improved method of preparing metal and metal articles for stamping and drawing in dies. Complete Specification. January 16.

1149. W. H. Hyatt and J. Henochsberg. Improvements in extracting gold and in apparatus therefor. January 16.

1257. J. Armstrong. Improvements in the extraction of silver, gold, lead, and zinc from their ores. January 17.

1271. H. R. Angel. Improvements in the reduction of refractory ores. January 18.

1316. A. J. Boulton.—From C. J. L. Otto. An improved manufacture of iron and steel. January 18.

1325. F. A. Ellis. Improvements in the drawing and planishing of tubes of aluminium alloy, and in means employed therefor. January 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1894.

801. H. R. Angel. Improvements in the extraction of lead with silver, gold, or other metals from ores blended with sulphide of zinc or otherwise. January 8.

1895.

2278. W. Kaufmann. Process for the production of metals and metallic alloys containing carbon and silicon. January 8.

2338. G. Robson and S. Crowder. Improvements in the treatment of finely divided substances, such as crushed ores, slime, tailings, and the like, for the separation and recovery of metals and metallic compounds therefrom. January 8.

2729. H. L. Sulman. Apparatus for recovery of precious metals from their solutions. December 11.

2730. H. L. Sulman. Precipitation of precious metals from their solutions. December 13.

2804. O. Imray.—From L. Diehl. Metallic mixtures and alloys for effecting electro-chemical decompositions. January 15.

3959. H. H. Lake. From P. Manhes. Process of desulphuration of castings and alloys of nickel and cobalt. January 22.

5295. R. C. Smith and A. B. Brown. Making chilled castings. January 22.

5958. C. G. T. Bennett, E. H. Shortman, and B. Bracey. Improved method of treating galvaniser's flux skimmings to recover ammonia and facilitate the extraction of the zinc, with apparatus for use therein. January 15.

6802. J. S. MacArthur and J. Yates. Extracting gold and silver from ores and the like. January 22.

16,920. B. C. Hinman. Process and apparatus for extracting gold from ores and other auriferous substances. December 26.

18,177. H. A. de Neuville. Process and apparatus for the extraction of gold and silver from their ores and from other auriferous substances. January 8.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

6565A. H. Tee. Improvements connected with the electrolysis of chlorides and other salts, and the evaporation of solutions. Filed December 19. Date claimed March 30, 1895.

24,165. L. Epstein. Process for hardening the active material on the positive plates of secondary voltaic batteries. December 17.

24,172. A. C. Iwanowski. Improvements in or connected with galvanic batteries. December 17.

24,394. A. C. Miles and B. F. de Morgenstern. Improvements in and relating to galvanic batteries. December 19.

24,447. C. M. Pielsticker. Improvements in the separation from their cathodes of electrolytically precipitated gold and silver from cyanide solutions. December 20.

24,516. L. Epstein. Improvements in secondary voltaic batteries. Complete Specification. December 21.

24,834. C. Therye and A. Oblasser. Improvements in electric accumulators. Filed December 27. Date applied for June 28, 1895, being date of application in France.

24,837. P. Jensen.—From H. C. F. Stormer. Improvement in the method and apparatus for washing alkali-amalgam obtained in electrolytic apparatus. December 27.

25,002. R. Heathfield and W. S. Rawson. Improvements in electrolytical apparatus. December 31.

1896.

130. R. J. Gulcher. Improvements in and relating to electric accumulators. Complete Specification. January 2.

475. W. C. Bersey. Improvements in electric accumulators. January 7.

477. C. N. Stewart. Improvements in electrical storage accumulators. January 7.

535. H. W. Headland. Improvements in primary and secondary batteries. January 8.

557. R. Collins and F. Cogan. Improvements in electric batteries. January 8.

710. A. C. Miles and B. F. de Morgenstern. Improvements in and relating to electric accumulators. January 10.

719. B. Willeox.—From La Soc. P'Accumulateur Fulmen. Improvements in electrical accumulators or storage batteries. January 10.

778. H. W. Headland. Improvements in secondary batteries. January 11.

780. H. Leitner. A new or improved method of manufacturing electrodes for secondary electric batteries. Complete Specification. January 11.

791. W. Walker, jun., F. R. Wilkins, J. Lones, and C. Vernon. Improvements in primary voltaic batteries. January 11.

842. S. O. Cowper-Coles. Improvements in and connected with the manufacture of electric conductors. January 13.

888. A. U. Alecock. An improved secondary battery or accumulator. January 13.

986. J. C. Graham. Improvements in the electro-deposition of metals. January 14.

1051. D. G. FitzGerald and W. C. Bersey. Improvements in voltaic batteries. January 15.

1068. J. C. Graham. An improved electrical process for recovering metals from weak solutions and for concentrating the electrolyte. January 15.

1069. C. Pollak. Improvements in or connected with electrical condensers. January 15.

1144. W. Heraeus. Improvements in electrodes for electrolytical purposes. January 16.

1228. D. M. Hawes. Improvements in the manufacture of battery cells or vessels to contain acids or other chemicals. January 17.

1238. P. A. Newton.—From C. Willms. Improvements in the manufacture of electric batteries. Complete Specification. January 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1894.

24,541. C. Kellner. Method of and apparatus for effecting electrolysis. December 26.

1895.

2999. The Cowper-Coles Galvanising Syndicate, Lim., and S. O. Cowper-Coles. Obtaining zinc from its ores, and the electro-deposition of zinc upon iron or other metals or alloys. January 15.

18,936. H. Leitner and E. Reicher. An improved process for the preparation of electrodes for primary, secondary, and dry batteries. January 15.

22,120. T. W. Allan, A. Powell, and C. J. Tibbits. Electric accumulators or storage batteries. December 31.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

24,418. E. S. Wilson and E. Stewart. Improvements in the separation and purification of colouring matter from crude cotton-seed oil. December 20.

24,544. G. MacDonald. Improvements in filtering, purifying, and decolorising oils, saccharine and other juices, alcoholic liquors, water, sewage, sewage effluents, and other liquids and fluids, and in materials and apparatus therefor. December 21.

24,714. A. E. Morgans. Improvements in the treatment of oleaginous and fatty substances of all kinds, and hydrocarbons, for purification and other purposes. December 24.

24,787. G. E. Wright and W. Monk. See Class V.

1896.

5. J. E. Bedford and C. S. Bedford. Improvements in the treatment of linseed oil. January 1.

799. H. Hinterberger. Apparatus for separating oil and air from water, and recovering the oil. January 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1894.

23,228. S. Crowder. Recovering oils or fatty substances from clays, sands, ores, mine slimes, or other finely-divided substances. December 31.

1895.

3466. J. T. A. Walker. Detergent or washing powder. January 8.

20,107. H. T. C. Kraus. Process of extracting oil from vegetable seed. December 26.

23,106. W. T. Whiteman.—From The Cleveland Linseed Oil Co. Purifying oil extracted by solvent from linseed or similar substance. January 8.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, ETC.

APPLICATIONS.

24,063. J. C. Sellars. Compound or material for use in connection with non-oleaginous protective coverings or paints. Complete Specification. December 16.

24,224. L. Kneche. Improvements in the manufacture of lac, varnish, and the like. Complete Specification. December 18.

24,324. T. Sheppardson. An anti-fouling and anti-corrosive composition for ships' bottoms and the like. December 19.

24,546. R. Langhans. Improvements in the manufacture or production of coatings composed of earthy oxides. December 21.

25,009. H. H. Lake.—From T. Benfield. An improved process of making oxide of lead. Complete Specification. December 31.

25,023. G. H. Smith. Improvements in the treatment or purification of red oxide of iron. December 31.

1896.

654. E. Serullas and F. Hourant. Improved process of obtaining and purifying gutta-percha. January 9.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

24,950. A. K. Y. Anderson and J. Mackintosh. A process for treating hides and skins in the manufacture of leather. Complete Specification. December 30.

24,968. J. B. Seammell and E. A. Muskett. Improvements in tanning. December 31.

1896.

289. J. Hudson. See Class XV.

COMPLETE SPECIFICATION ACCEPTED.

1895.

22,714. C. Knees and D. W. Alexander. Process for tanning hides. January 22.

XV.—AGRICULTURE AND MANURES, ETC.**APPLICATIONS.**

289. J. Hudson. A process for rendering waste leather soluble and applicable as a manure. January 4.

COMPLETE SPECIFICATION ACCEPTED.

1895.

21,627. L. Tralls and E. Burmeister. Treatment and manufacture of manure and in preservatives and disinfectants for manure. December 26.

XVI.—SUGARS, STARCHES, GUMS, ETC.**APPLICATIONS.**

24,456. C. Hellfrisch. Process for the treatment of potato starch with chlorine under heating. Complete Specification. December 20.

24,544. G. MacDonald. See Class XII.

1896.

333. E. Müller and C. Müller. Process for clarifying vegetable juices. January 6.

1101. M. Sachs. An improved process for treating the by-products of sugar works and sugar refineries. Complete Specification. January 16.

COMPLETE SPECIFICATION ACCEPTED.

1895.

7171. H. Reichardt and J. Bueb. Process for manufacturing cyanides out of molasses and lyes resulting from beetroot-molasses. January 8.

XVII.—BREWING, WINES, SPIRITS, ETC.**APPLICATIONS.**

24,387. D. Young. From C. Bullock and C. M. Reed. An improved method of and apparatus for purifying and refining alcoholic liquors. Complete Specification. December 19.

1896.

318. W. Adlam and A. Wilson. An improved cylinder for kilning malt. January 6.

766. E. Davies and H. M. H. Goodfellow. Improvements in the treatment of spent hops for preparing the same for use as a stuffing material, and in machinery therefor. January 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

17,496. H. Elion. Manufacture of yeast. January 22.

20,997. S. Kuhlmann. Brewing, and apparatus therefor. January 22.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.**APPLICATIONS.****A.—Chemistry of Foods.**

24,153. J. Rose. Improvements in the manufacture of cheese. December 17.

24,156. S. S. Bromhead.—From V. Durant. Improvements in apparatus for effecting a rapid separation of the fatty matter in milk without the aid of rotation or beat. December 17.

24,282. W. P. Thompson.—From M. Braumann and A. Braumann. Improvements in the preservation of green vegetables and the like. Complete Specification. December 18.

24,293. H. J. Haddan.—From E. Freixa. An improved process of manufacture of nitrogenised water. Complete Specification. December 18.

24,552. J. Pleines. Improvements in the manufacture of baking powder. December 21.

24,854. W. Robinson. Improved milk steriliser. December 28.

B.—Sanitary Chemistry.

24,168. G. D. Yates. Improvements in softening water for domestic or other use, and in compositions therefor. December 17.

24,544. G. MacDonald. See Class XII.

1896.

821. J. H. Williams. Apparatus and process for purification, softening, or hardening of water for domestic, manufacturing, or other purposes. January 13.

1038. R. E. von Lengerke. Improvements in arrangements and apparatus for filtration of sewage. January 15.

COMPLETE SPECIFICATIONS ACCEPTED.**A.—Chemistry of Foods.**

1895.

4886. W. H. Thew and J. H. Hooker. Preparation of peptonised milk and cocoa. January 15.

6257. J. L. Johnston and Boyril, Lin. A new or improved method of obtaining and preserving the soluble albumen of animal food. January 22.

13,176. F. V. Friderichsen. Process of manufacturing fodder. December 26.

22,887. C. M. U. Dahle. Process for the preservation and preparation for transit of fish liver. January 8.

B.—Sanitary Chemistry.

1895.

166. F. P. Candy. Improvements in and in apparatus for use in connection with the purification of sewage and impure waters. December 31.

3360. H. T. Wright. Apparatus for softening and purifying water. December 26.

4514. P. Boisserand. Sterilising and purifying liquids. December 26.

C.—Disinfectants.

1895.

5358. J. B. McArthur. Disinfecting materials. January 15.

XIX.—PAPER, PASTEBOARD, ETC.**APPLICATIONS.**

24,272. A. Duffek and A. Merrel. Improvements in the manufacture or preparation of cellulose suitable as a raw material for paper. Complete Specification. December 18.

24,275. T. A. Marshall.—From G. Smidth. Improvements in separating fibres from the waste liquors of paper-making machinery. Complete Specification. December 18.

24,421. J. White. Improvements in apparatus for straining paper pulp. December 20.

1896.

210. H. H. Lake.—From E. Berland and J. Girard. Improvements in the manufacture of paper pulp from the broom plant. January 3.

COMPLETE SPECIFICATION ACCEPTED.

1894.

24,826. H. Sweetapple. Manufacture of vegetable parchment paper. December 26.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

24,517. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of hydroxy phenacetine-salicylate. December 21.

24,615. M. Woolf. The preparation and production of essences or extracts from vegetables. December 23.

24,848. H. H. Lake. — From O. O. B. Froelich. Improvements relating to the preparation of compounds of fluoride of antimony. December 27.

1896.

9. W. Majert. The manufacture or production of an ammonium compound of casein. Complete Specification. January 1.

21. W. Majert. Improvements in the manufacture or production of vanillin. Complete Specification. January 1.

529. C. J. Caspers. Improved process for the preparation of artificial musk. January 8.

601. T. O. Kent. A new or improved extract of coffee, and the method of preparing the same. January 9.

816. E. Durkopf. An improved process of producing methyleneditannic acids from formaldehyde and tannin. January 11.

1202. J. Y. Johnson. — From Vereinigte Chininfabriken, Zimmer and Co. The manufacture or preparation and production of new medicinal compounds. January 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1894.

24,446. M. Otto and A. Verley. Manufacture of perfumes. December 26.

1895.

5135. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of a sweet compound and of certain intermediate products therefor. January 15.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

24,440. W. Friese-Greene. Improvements in the manufacture of sensitised paper suitable for photographic purposes. December 20.

1896.

371. A. M. Clark. — From Lembach and Schleicher. Improvements in photographic developers. January 6.

450. G. J. Ball and B. F. C. Costelloe. An improved method in photography. January 7.

507. J. B. Findlay. Improved screens for use in photo-mechanical process work, and in the three-colour process of photography. January 7.

871. W. Haydon. Certain new and useful improvements in preventing halation in photographic dry plates. January 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

7188. B. J. B. Mills. — From A. Lumière and L. Lumière. An improved photographic process giving,

without transfer, images with their half tints, and the application of this process to photography in colours. January 22.

21,989. H. E. Mendelsohn. Means for producing photographs resembling engravings. December 26.

XXII.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

24,209. A. J. Boulton. — From M. Reuland. Improvements in or relating to blasting or other cartridges. December 17.

24,725. W. Weiffenbach. Improvements in the manufacture of pyrotechnic compounds. Complete Specification. December 24.

24,847. H. H. Lake. — From W. Greaves and E. M. Hann. Improvements in or relating to explosives. December 27.

1896.

949. W. Theodorovic. Improved process for reducing to small fabric fragments cellulose bodies, for facilitating the nitration thereof, and for other purposes, and the production of explosives from such reduced and nitrated cellulose bodies. Complete Specification. January 14.

1226. R. H. Courtenay. Improvements in explosive compounds, with means to increase the explosive force of gun-cotton, ordinary gunpowder, and other explosives. January 17.

1312. O. Imray. — From F. C. Glaser. Manufacture of a new gunpowder. January 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

4769. A. Luck and A. H. Purnford. Manufacture of nitrocellulose and compounds thereof. January 8.

22,327. H. Siebeck. Process and apparatus for igniting quick-matches or fuses. December 31.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

1040. F. G. Waller. Collecting and analysing gases. January 22.

COMPLETE SPECIFICATION ACCEPTED.

1895.

20,051. E. Jahr. Process and apparatus for testing butter and other fats. December 31.

PATENTS UNCLASSIFIABLE.

APPLICATIONS.

24,163. L. Grote. An improved process of manufacture of a mouldable mass from asbestos fibre or other fibrous material. December 17.

25,013. W. L. Woods. An improved plastic composition and process of combining the same. Complete Specification. December 31.

LIST OF COUNCIL AND OFFICERS.

President.

Thomas Tyrer, Stirling Chemical Works, Stratford, E.

Vice-Presidents.

Sir F. A. Abel, Bart., F.R.S., 2, Whitehall Court, London, S.W.

Horace T. Brown, F.R.S., 52, Nevein Square, Kensington, S.W.

John Calderwood, Gowanlea, Spencer Park, Wandsworth, S.W.

Chas. Dreyfus, Clayton, Manchester.

Dr. A. Dupré, F.R.S., Caxton Street, Westminster, S.W.

Sir John Evans, K.C.B., F.R.S., Nash Mills, Hemel Hempstead, Herts.

Thos. Fairley, 17, East Parade, Leeds.

Boverton Redwood, 4, Bishopsgate Street Within, London, E.C.

Sir H. E. Roseoe, F.R.S., 10, Bramham Gardens, Kensington, S.W.

E. C. C. Stanford, Glenwood, Dalnair, N.B.

Dr. T. E. Thorpe, F.R.S., 61, Ladbroke Grove, Notting Hill, W.

Prof. W. A. Tilden, F.R.S., 9, Ladbroke Gardens, Notting Hill, W.

Ordinary Members of Council.

C. A. Fawsitt, Atlas Chemical Works, East Nelson Street, Glasgow.

R. Le Neve Foster, The Firs, North Road, Droylsden, Manchester.

Douglas Herman, Ecclestone Park, Prescott, Lancashire.

David Howard, Devon House, Buckhurst Hill, Essex.

Prof. A. K. Huntington, King's College, Strand, W.C.

C. C. Hutchinson, Engineering Works, Stratford, E.

Ivan Levinstein, Minshull Street, Manchester.

J. S. McArthur, 108A, Hope Street, Glasgow.

Sir Robt. Pullar, Perth, N.B.

G. N. Stoker, Laboratory, Somerset House, Strand, W.C.

Wm. Thorp, 24, Crouch Hall Road, Crouch End, N.

Frank Wilson, Brewery, Castle Street, Long Acre, W.C.

Chairmen and Secretaries of Sections (Ex-officio Members of Council).

Liverpool :

Chairman . . . Dr. G. Schack-Sommer, 323, Vauxhall Road, Liverpool.

Secretary . . . Dr. T. L. Bailey, University College, Liverpool.

London :

Chairman . . . B. E. R. Newlands, 27, Mincing Lane, E.C.

Secretary . . . John Heron, 110, Fenchurch Street, E.C.

Manchester :

Chairman . . . George E. Davis, Sandilands, Knutsford, Cheshire.

Secretary . . . J. Carter Bell, Bank House, Higher Broughton, Manchester.

Newcastle :

Chairman . . . G. T. France, Friar's Goose Works, Gateshead.

Secretary . . . Saville Shaw, Durham College of Science, Newcastle-on-Tyne.

New York :

Chairman . . . Alfred H. Mason, 59-61, Maiden Lane, New York, U.S.A.

Secretary . . . Dr. H. Schweitzer, 159, Front Street, New York, U.S.A.

Nottingham :

Chairman . . . F. J. R. Carulla, 84, Argyll Terrace, Derby.

Secretary . . . J. T. Wood, 29, Musters Road, West Bridgeford, Nottingham.

Scotland :

Chairman . . . Dr. John Clark, 138, Bath Street, Glasgow.

Secretary . . . J. Stanley Muir, Chemical Laboratory, The University, Glasgow.

Yorkshire :

Chairman . . . C. F. Tetley, The Brewery, Leeds.

Secretary . . . H. R. Procter, Thornleigh, Ilkley, Yorks.

Honorary Treasurer.

E. Rider Cook, East London Soap Works, Bow, E.

Honorary Foreign Secretary.

Ludwig Mond, F.R.S., 20, Avenue Road, Regent's Park, N.W.

General Secretary.

Chas. G. Cresswell, Palace Chambers, Westminster, S.W.

Editor.

Watson Smith, 34, Upper Park Road, Haverslock Hill, N.W.

LIST OF MEMBERS.

A

- Abbott, John, 6, Chichester Terrace, Brighton, Chemical Manufacturer.
- Atcl, Sir F. A., Bart., F.R.S., 2, Whitehall Court, London, S.W., Consulting Chemist.
- Acland, Sir H. W., Bart., F.R.S., Radcliffe Library, Oxford, Librarian.
- Adams, Arthur, Kelvin House, Edgbaston Road, Smethwick, near Birmingham, Science Lecturer.
- Adams, M. A., Ashford Road, Maidstone, Kent, Public Analyst.
- Adamson, G. P., 233, Reeder Street, Easton, Pa., U.S.A., Manufacturing Chemist.
- Adcock, S. R., Minas de Rio Tinto, Provincia de Huelva, Spain, Analytical Chemist.
- Adler, Dr. Leon N., Adler Colour and Chemical Works, 96-98, Maiden Lane, New York, U.S.A., Manufacturing Chemist.
- Adrianee, John S., 126, East 34th Street, New York, U.S.A., Analytical Chemist.
- Affleck, Dr. J., Springfield, Garston, near Liverpool, Alkali Inspector.
- Aikman, Charles M., 128, Wellington Street, Glasgow, Analytical Chemist.
- Aitken, Dr. A. P., 57, Great King Street, Edinburgh, Consulting Chemist.
- Aitken, J. B., Gerard's Fold Chemical Works, Widnes, Chemical Manufacturer.
- Albright, G. S., The Elms, Park Road, Edgbaston, Chemical Manufacturer.
- Albright, W. A., Mariemont, Edgbaston, Birmingham, Chemical Manufacturer.
- Alecock, Jno. W., Central Brewery, Mott Street, Birmingham, Maltster and Brewer.
- Aldrick, Edwin John, 53, Alpha Road, West Ferry Road, Millwall, E., Chemical Works Clerk.
- Alexander, W. T., 20, Booth Street, Moseley Street, Manchester; and Crummock Bank, Victoria Crescent, Eccles, Drysalter.
- Allan, F. H., Tielke, Portobello House, Wakefield, Analytical Chemist.
- Aldred, C. H., 6, Heavitree Road, Plumstead Common, Kent, Analytical Chemist.
- Allen, A. H., Sydenham Cottage, Park Lane, Sheffield, Consulting Chemist.
- Allen, Edw. W., Dover Mills, Glossop, Derbys-hire, Paper Stainer's Manager.
- Allen, G. J., Laboratory, 55-56, Barton Arcade, Manchester, and (Journals) Stonclea, Swinton Park, near Manchester, Analytical and Consulting Chemist.
- Allen, J., 164, Upper North Street, Poplar, London, E., Manufacturing Chemist.
- Allen, R. L., Newton Farm, Middlewich, Cheshire, Analytical Chemist.
- Allen, Walter S., 24, West Street, Boston, Mass., U.S.A., Clerk to State Board of Gas Commissioners.
- Allen, Walter W., c/o The Pueblo Smelting and Refining Co., Pueblo, Colorado, U.S.A., Metallurgical Manager.
- Allen, Wm., Evenley Hall, Brackley, North Hants.
- Allen, Wm. N., 2, Chesnut Street, Philadelphia, Pa., U.S.A., Chemical Manufacturer.
- Allhusen, A., Gateshead-on-Tyne, Chemical Manufacturer.
- Allison, G. H., c/o Richardson Bros. & Co., 30, Donegall Place, Belfast, Chemical Works Manager.
- Alliott, J. B. Messrs. Manlove, Alliott, and Co. Ltd., Nottingham, Mechanical Engineer.
- Allison, Wm. O., 72, William Street, New York, U.S.A., Publisher of "Oil Paint and Drug Reporter."
- Alpar, Agop, Smyrna, Asia Minor, Morphia Manufacturer.
- Alsberg, M. (Sondheim, Alsberg, & Co.), P.O. Box 2437, New York, U.S.A., Colour Manufacturer.
- Anderson, Eugene E. J., 4, Muirpark Gardens, Partick, Glasgow, Gas Manager.
- Anderson, J. M. T., Explosives Co. Ltd., Stowmarket, Suffolk, Gun-cotton Works Manager.
- Anderson, Robt. T. R., 618, Gallowgate Street, Glasgow, Technical Chemist.
- Anderson, W. Carriek, jun., Mavisbank, Partick Hill, Glasgow, University Chemical Assistant.
- Anderson, Wm., 47, Regent Arch, Edinburgh, Drysalter.
- Anderton, G. H., Howendyke, Howden, Yorks, Chemical Manufacturer.
- Andrews, C. W., c/o The John Crerar Library, Wabash Avenue and Washington Street, Chicago, Ill., U.S.A., Chemical Instructor.
- Angell, J., 6, Beaconsfield, Derby Road, Fallowfield, Manchester, Chemical Lecturer.
- Annandale, C. J. R., The Briary, Shotley Bridge, Co. Durham, Paper Maker.
- Annandale, J. H., Polton, Midlothian, N.B., Paper Maker.
- Annison, R. H., 16, Water Lane, Tower Street, London, E.C., Master Lighterman.
- Anslacher, L. A., P.O. Box 1934, New York, U.S.A., Colour Manufacturer.
- Ansdell, G., 10, Gledhow Gardens, South Kensington, S.W., Analytical Chemist.
- Ansdell, T. C., Kearsley Cottage, Farnworth, Bolton, Manufacturing Chemist.
- Anselm, Dr. Fritz, c/o Actien Gesellschaft für Anilin Fabrikation, Treptowerbrücke 33, Berlin, S.O., Colour Chemist.
- Appleby, Prof. W. R., 911, 5th Street, S.E., Minneapolis, Minn., U.S.A., Professor of Mining and Metallurgy.
- Appleton, H. A., c/o Dr. Hess, Oil and Stearine Works, Newlay, near Leeds, Analytical Chemist.
- Archbold, Dr. George, 121-123, Front Street, New York City, U.S.A., Analytical Chemist.
- Archbutt, L., The Vews, Madeley Street, Derby, Analytical Chemist.
- Arding, Francis, 5, Jeffreys Square, St. Mary Axe, London, E.C., Secretary to Ammonia Gas Purification Co., Ltd.
- Armstrong, Rt. Hon. Lord, F.R.S., Newcastle-upon-Tyne, Civil Engineer.
- Ascough, Jesse, The Grange, Laurel Road, Handsworth, Birmingham, Borax Manufacturer.
- Ashplant, Wm. Gilbert, Palmer House, Torrington, North Devon, Manure Manufacturer.
- Ashton-Bost, W.D., Cartvale Chemical Works, Paisley, N.B., Chemical Manufacturer.
- Ashwell, H., 91, Waterloo Crescent, Nottingham, Bleacher and Dyer.
- Ashwell, J. H., 91, Waterloo Crescent, Nottingham, Bleacher and Dyer.
- Ashworth, Arthur, Fernhill Chemical Works, Bury, Lancashire, Chemical Manufacturer.

Ashworth L., The Orchard, Manchester Road, Bury, Lancashire, Bleacher, Dyer, and Finisher.
 Atkins, C. E., East Ham House, East Ham, Essex, Chronometer Maker.
 Atkinson, A. J., 44, Loudoun Square, Cardiff, Analytical Chemist.
 Atkinson, R. W., 44, Loudoun Square, Cardiff, Technical Chemist.
 Attfield, Dr. J., F.R.S., Ashlands, Watford, Hertfordshire, Professor of Practical Chemistry.
 Auchterlonie, Wm., jun., Canal Bank House, Paisley, N.B., Analytical Chemist.
 Auer, Dr. H., V. Sas Utea 10, Budapest, Hungary, Technical Chemist.
 Austen, Prof. Peter T., 876, President Street, Brooklyn, N.Y., U.S.A., Professor of Chemistry.
 Aykroyd, H. E., Ashwell, Toller Lane, Bradford, Yorks, Dyer.

B

Babington, Percival, 19, Culverdon Park Road, Tunbridge Wells, Analytical Chemist.
 Bache, Arthur E., 7, Park Row, Greenwich, S.E., Sanitary Engineer.
 Bachke, Anton S.O., Røros Vaerke, Røros, Norway, Metallurgical Engineer.
 Bacon, Nathaniel T., Peace Dale, Rhode Island, U.S.A., Chemical Engineer.
 Bailey, Edwin M., 6, Pumpherston, Mideclder, N.B., Technical Chemist.
 Bailey, Dr. G. H., Marple Cottage, Marple, Cheshire, Chemical Lecturer.
 Bailey, Thos., 25, High Street, Hull, Seed Crusher.
 Bailey, Dr. T. L., University College, Brownlow Street, Liverpool, Lecturer on Technological Chemistry.
 Bailey, Sir W. H., Albion Works, Salford, Manchester, Chemical Engineer.
 Bailey, Walter P., c/o G. W. Welton, Rabida 21, Seville, Spain, Chemist.
 Bailey, Wm., Gracedieu, Alloa, N.B., Earthenware Manufacturer.
 Baird, H. Harper, 14, Cross Street, Hatton Garden, London, E.C., Laboratory Furnisher.
 Baird, Wm., c/o Lewis Berger and Sons, Ltd., Homerton, N.E., Technical Chemist.
 Baird, W. Raymond, 271, Broadway, New York, U.S.A., Patent Lawyer.
 Bairstow, John, Barley, Queen's Park, Chester, Chemical Works Manager.
 Baker, Harry, Vicarage Road, Langley Green, near Birmingham, Analytical Chemist.
 Baker, Julian L., Stamford, Headham Road, Upper Tooting, S.W., Sugar Chemist.
 Baker, Theodore, Box 97, Belford, N.J., U.S.A., Analytical Chemist.
 Bald, J. H., Braddock, Pa., U.S.A., Steel Works Chemist.
 Bale, Fred., Coventry Hospital, Droitwich, Science Teacher and Chemist.
 Ballard, Ernest, Colwall, Great Malvern, Malt Vinegar Brewer.
 Ballard, E. G., Newton Lane, Hoole, Chester, Alkali Works Inspector.
 Ballantyne, H., 250, Renfrew Street, Glasgow, Analytical Chemist.
 Ballinger, Jno., Free Library, Cardiff, Librarian.
 Baly, E. C. C., University College, Gower Street, W.C., Analytical Chemist.
 Bamber, H. K., 9, Victoria Street, London, S.W., Consulting Chemist.
 Bamber, H. K. G., Ilex House, Starcross, Devon, Portland Cement Works Chemist and Manager.
 Banister, H. C., Elmhurst, Blundellsands, near Liverpool, Chemical Works Manager.
 Banks, Arthur J., c/o F. W. Fellowes, 62, Chancery Lane, London, W.C., Brewer's Analyst.
 Banks, Jno. H., c/o Ricketts and Banks, 104, John Street, New York, U.S.A., Mining Engineer.

Bannan, John F., North Andover, Mass., U.S.A., Chemist (Woollen Mill).
 Banner, Samuel, 4, Ivanhoe Road, Liverpool, Petroleum Merchant.
 Bannister, R., The Laboratory, Somerset House, London, W.C., Analytical Chemist.
 Bannister, W., Victoria Lodge, Cork, Ireland, Manufacturing Chemist.
 Barbour, T. F., 204, George Street, Glasgow, Chemist.
 Barclay, H., Calder Ironworks, Coatbridge, N.B., Ironworks Manager.
 Barden, Alf., Far Bank, Shelley, near Huddersfield, Glue and Size Maker.
 Barden, Sam., Far Bank Farm, Shelley, near Huddersfield, Glue and Size Manufacturer.
 Bardsley, Robt., Messrs. Jewsbury and Brown, Ardlwick Green, Manchester, Mineral Water Manufacturer.
 Bardwell, Fred. L., Massachusetts Institute of Technology, Boston, Mass., U.S.A., Assistant Professor of Chemistry.
 Barford, E. A., 3, Brook Street, Luton, Beds, Straw Plait Dyer and Bleacher.
 Barlow, Clinton W., 38, Irving Place, Brooklyn, N.Y., U.S.A., Merchant.
 Barnes, Edw. A., c/o The National Explosives Co., Lim., Hayle, Cornwall, Technical Chemist.
 Barnes, H. J., Phoenix Chemical Works, Hackney Wick, E., Manufacturing Chemist.
 Barnes, J., Marl Terrace, Acerrington, Lancashire, Analytical Chemist.
 Barnes, Jonathan, 1, Trafalgar Street, Great Clowes Street, Manchester, Analytical Chemist.
 Barr, J., Dinting Vale, Dinting, Derbyshire, Chemical Manager.
 Barracough, T. C., 20 Bucklersbury, London, E.C., Analytical Chemist.
 Barracough, Wm. H., Harecourt Lodge, Chapelton, Sheffield, Engineer.
 Barratt, W. S., St. Margaret's Schools, Whalley Range, Manchester, Science Teacher.
 Barrett, Arthur A., 185, Corso Vittorio Emanuele, Messina, Sicily, Manufacturer of Essential Oils.
 Barrie, D. McLaurin, New Chimes Gold Mining Company, per private bag, Johannesburg, S.A.R., Analytical Chemist.
 Barrington, Edw. C., 18, Earlsfort Terrace, Dublin, Ireland, Soap Manufacturer.
 Barton, G. E., Hatfield, Mass., U.S.A., Explosives Chemist.
 Baskerville, Dr. Chas., University of North Carolina, Chapel Hill, N.C., U.S.A., Assistant Professor of Chemistry.
 Bassett, H., 26, Belitha Villas, Barnsbury, N.
 Batchelor, Telford C., 8, Baron's Court Road, West Kensington, W., Mechanical Engineer.
 Bate, William, c/o National Explosives Co., Ltd., Hayle, Cornwall, Technical Chemist.
 Bateman, Jno., c/o J. C. and J. Field, Lim., Lambeth Marsh, S.E., Candle and Acid Works Manager.
 Bateman, R. W., 90, Cazenove Road, Stoke Newington, N., Leather Manufacturer.
 Bateson, Percy, Oakfield, Penny Lane, Wavertree, Liverpool, Technical Chemist.
 Batty, R. B., Wharfedale, Erdington, near Birmingham, Nickel Works Manager.
 Baum, Henry, 145, Dickenson Road, Rusholme, Manchester, Chemist.
 Bavay, Aug. de, Victoria Brewery, Melbourne, Australia, Brewer.
 Baxter, W. H., 11, High Road, Streatham, S.W., Brewery Manager.
 Bayne, Prof. Jas., Chemical Laboratory, Royal Veterinary College, Camden Town, N.W., Professor of Chemistry.
 Baynes, J., Royal Chambers, Scale Lane, Hull, County and Borough Analyst.
 Beach, E. J., 1183, Locust Street, Dubuque, Iowa, U.S.A., Soap Manufacturer.
 Beadle, Clayton, 4, New Court, Lincoln's Inn, W.C.; and Beadonwell, Belvedere, Kent (Journals), Consulting Chemist.
 Bealey, Adam C., c/o R. Bealey & Co., Radcliffe, Lancashire, Bleacher and Alkali Manufacturer.

- Beaman, H. S., 18, Maxilla Gardens, North Kensington, W., Brewer and Analytical Chemist.
- Beanes, E., Moutlands, Paddock Wood, Kent, and (Journals) 119, Ashley Gardens, London, S.W., Manufacturing Chemist.
- Beaven, E. S., 5, Borcham Terrace, Warminster, Wilts, Maltster.
- Bechi, Guido de, 13, Rue de la Chaussée D'Antin, Paris, France, Director of the "Société la Saturnine."
- Beck, H., 22, Bush Lane, E.C., Chemical Agent.
- Beckett, G. H., c/o Alf. Nobel, San Remo, Italy, Analytical Chemist.
- Beckett, J. H., Corbar Hill House, Buxton, Manufacturing Chemist.
- Beclun, Lezin A., McCall Post Office, Parish of Ascension, Louisiana, U.S.A., Sugar Engineer.
- Bedford, Chas. S., Broomleigh, Chapel Lane, Headingley, Leeds, Manufacturing Chemist.
- Bedford, J., Woodhouse Cliff, Leeds, Chemical Manufacturer.
- Bedford, Jas. E., Messrs. Wood and Bedford, Kirk-stall Road, Leeds, Manufacturing Chemist.
- Bedson, Prof. P. P., Durham College of Science, Newcastle-on-Tyne, Professor of Chemistry.
- Belby, G., St. Kitts, Slateford, N.B., Chemical Engineer.
- Bell, C. Lowthian, Lanthorpe, Middlesbrough-on-Tees, Soda and Iron Manufacturer.
- Bell, Sir Lowthian, Bart., F.R.S., (Journals) Rounton Grange, Northallerton; and (subs.) c/o Bell Bros., Middlesbrough, Iron and Chemical Manufacturer.
- Bell, J. Carter, Bank House, The Cliff, Higher Broughton, Manchester, Public Analyst.
- Bell, J. Ferguson, Stafford, Gas Engineer.
- Bell, Percy Carter, 13, Ann Street, Park Row, New York, U.S.A., Analytical Chemist.
- Bell, T. Hugh, Middlesbrough-on-Tees, Soda and Iron Manufacturer.
- Bendix, D., The British Alizarin Co., Limited, Silvertown, Victoria Docks, London, E.; Journals to 371, Romford Road, Forest Gate, E., Managing Chemist.
- Benger, F. B., The Grange, Knutsford, Cheshire, Manufacturing Chemist.
- Benjamin, Dr. M., 589, West End Avenue, New York, U.S.A., Consulting Chemist, A.M., Ph.D.
- Bennett, Thos., Birch Vale, near Stockport, Calico Printer.
- Bennie, J. W., 2, Limesford Road, Nunhead, S.E., Metallurgist.
- Bentz, Ernest, 5, Demesne Road, Whalley Range, Manchester, Lecturer on Dyeing.
- Berenger, J. J., Basset Road, Camborne, Cornwall, Metallurgist.
- Berk, Fred. W., 1, Fenchurch Avenue, London, E.C., Chemical Manufacturer.
- Bernard, Jas., jun., Casal das Rollas, Olivaes, Lisbon, Chemical Works Manager.
- Bernays, J., 96, Newgate Street, London, E.C., Civil Engineer.
- Berry, E. F., Casa Balestra, Bordighera, Italy, Technical Chemist.
- Berry, G. F., Atlas Chemical Works, West Ferry Road, Millwall, E., Chemical Works Manager.
- Bertram, H. Conrad, c/o Josiah Macy's Sons, 191, Front Street, New York, U.S.A., Oil Refiner.
- Best, Dr. T. T., Hardshaw Brook Chemical Works, St. Helens, Lancashire, Technical Chemist.
- Bevan, E. J., 4, New Court, Lincoln's Inn, London, W.C., Public Analyst and Consulting Chemist.
- Bevan, S. Howel, Hillside, Llanelly, South Wales, Chemical Engineer.
- Beveridge, J., Sulphate Pulp Mills, Hjerpen, Sweden, Pulp and Paper Manufacturer.
- Bhaduri, K., c/o S. K. Lahiri and Co., 51, College Street, Calcutta, India, Analytical Chemist.
- Bibby, E. V., Garston Copper Works, Garston, near Liverpool, Copper Smelter.
- Bickerdike, W. E., Clayton Grange, Wiltshire, near Blackburn, Manufacturing Chemist.
- Bicknell, G. Arthur, 839, East Madison Avenue, Cleveland, Ohio, U.S.A., Analytical Chemist.
- Biggart, J. Wm., 29, Catheart Street, Greenock, N.B., Analytical Chemist.
- Biggart, Wm. L., Messrs. C. M. Biggart and Co., 15, Gordon Street, Glasgow, Public Analyst.
- Biggs, B., Vestry House, Lawrence Pountney Hill, London, E.C., Chemical Merchant.
- Bihn, G. F., Pennsylvania Salt Manufacturing Co., Philadelphia, U.S.A., Chemical Manufacturer.
- Billing, H. S., 5, Regent Terrace, Plympton, South Devon, Analytical and Managing Chemist.
- Bindshedler, Dr. R., Basle Chemical Works Bindshedler, Basle, Switzerland, Colour Manufacturer.
- Binney, H. A., Rainhill, near Liverpool, Glass Manufacturer.
- Birch, R. W. Peregrine, 5, Queen Anne's Gate, Westminster, S.W., Civil Engineer.
- Birch, Wm., Milton Street Ironworks, Lower Broughton, Manchester, Machinist.
- Bird, Henry, South Down House, Millbrook, Plymouth, Metallurgist.
- Bird, R., Eilerslie, Roath, Cardiff, Tar Distiller.
- Bird, Wm. R., 12, Gordon Road, New Swindon, Wilts, Analytical Chemist.
- Birley, R. K., Messrs. Chas. Macintosh & Co., Cambridge Street, Manchester, India-rubber Manufacturer.
- Bischof, Gustav, 4, Hart St., Bloomsbury, London, W.C., Technical Chemist.
- Bischoff, Dr. Ernst, 87-89, Park Place, New York, U.S.A., Chemist.
- Bishop, A. Conway, Three Mills Lane, Bromley-by-Bow, London, E., Manufacturing Chemist.
- Bishop, Fred, c/o Linlithgow Oil Co., Ltd., Linlithgow, N.B., Technical Chemist.
- Bishop, G. A., Gartverrie Fireclay Works, Coathridge, N.B., Mining Engineer.
- Bishop, Jos. T. F., 123, Cottenham Street, Chorlton-on-Medlock, Manchester, Agent.
- Black, Wm., Stamrigg, Airdrie, N.B., Coal Master.
- Black, Wm., 9, St. Edmund's Road, Gateshead, Analytical Chemist.
- Blackmore, H. S., 206, South Ninth Avenue, Mount Vernon, N.Y., U.S.A., Chemist (Pure Aluminium and Chemical Company).
- Blackwell, G. G., The Albany, Oldhall Street, Liverpool, Chemical Merchant.
- Blagden, W. G., 1, Fenchurch Avenue, London, E.C., Chemical Merchant.
- Blake, Arthur, Dean House, Redhill, Surrey, Veterinary Surgeon.
- Blake, C. A., 47, Piccadilly, London, W., Pharmaceutical Chemist.
- Blake, Jas., Thames Sugar Refinery, Silvertown, London, E., Sugar Refinery Manager.
- Blakey, A. J., Dudbridge Mills, Stroud, Gloucestershire, Foreman Dyer.
- Blass, Edw., Essen (Ruhr), Germany, Civil Engineer.
- Bleas, John, c/o Langworthy Bros. and Co., Lim., Greengate Mills, Salford, Dyer and Calico Printer.
- Blenkinsop, W., Garden Wharf, Battersea, London, S.W., Manufacturing Chemist.
- Bles, A. J. S., 32, Chorlton Street, Manchester, Chemical Merchant.
- Bloede, Victor G., Carroll Station, Baltimore, Md., U.S.A., Manufacturing Chemist.
- Bloomer, Fred. J., 15, Broderick Road, Tooting, S.W., Technical Chemist and Nickel Works Manager.
- Bloomfield, R., Tellara Factory, via Dhaka Chumparun, Bengal, India, Indigo Planter.
- Blount, Bertram, Chemical Laboratory, Broadway, Westminster, S.W., Analytical Chemist.
- Bloxam, A. G., The Goldsmiths' Institute, New Cross, S.E., and (Journals) 16, Bolingbroke Road, West Kensington, W., Analytical Chemist.
- Bloxam, W., Popplewell, Royal Naval College, Greenwich, S.E., Chemist.
- Blundstone, E. R., 14, Great Smith Street, Westminster, S.W., and (Journals) Cornwall Lodge, St. James' Road, New Hampton, Middlesex, Consulting and Analytical Chemist.
- Blyton, J., 12, Cromford Court, Market Street, Manchester.

- Boake, A., Southwood Lawn, Highgate, N., Manufacturing Chemist.
- Boake, Edmund J., 11, Christchurch Road, Crouch End, N., Manufacturing Chemist.
- Board, J. T., Distillery, Cheese Lane, Bristol, Distiller.
- Bohm, Jos. A., c/o Actien Gesellschaft für Chemische Industrie, Mannheim, Germany, Manager.
- Bonn, J. Edwin, High Street, Brading, Isle of Wight, Chemist.
- Bookman, Dr. S., 9, East 62nd Street, New York, U.S.A., Chemist.
- Boor, Leonard G., 1 and 2, Artillery Lane, London, E.C., Chemical Merchant.
- Booth, F. W., Station Road, Whittington Moor, near Chesterfield, Analytical Chemist.
- Booth, Geo., Irk Vale Dyeworks, Middleton, near Manchester, Yarn Dyer.
- Booth, Robt., 110, Cannon Street, London, E.C., Engineer.
- Boothby, Chas., c/o J. L. Wade & Co., Manor House Wharf, Vauxhall, S.W., Analytical Chemist.
- Borland, John, Etruria, Kilmarnock, N.B., Pharmaceutical Chemist.
- Borland, W. D., Beacon Lodge, Green Street Green, near Dartford, Kent, Explosives Chemist.
- Bothamley, C. H., Wentworth, Weston-super-Mare, Somerset, County Director of Technical Instruction.
- Bott, Dr. Wm., Singapore, S.S., Science Lecturer.
- Böttinger, H. T., Elberfeld, Germany; and (subs.) c/o Bryce and Rumpf, 20, Booth Street, Manchester, Colour Manufacturer.
- Bottle, Alex., 4, Godwyne Road, Dover, Pharmaceutical Chemist.
- Boulton, H. E., 64, Cannon Street, London, E.C., Chemical Manufacturer.
- Boulton, James, Crayford Mills, Stratford, E., Manufacturing Chemist.
- Boulton, S. B., 64, Cannon Street, London, E.C., Chemical Manufacturer.
- Boulton, T. S., 14, Freegrove Road, Caledonian Road, N., Manager.
- Bow, R. H., 7, South Gray Street, Edinburgh, Civil Engineer.
- Bowen, S. B., Brickfield Chemical Works, Llanelly, South Wales, Chemical Manufacturer.
- Bower, Frank, 164, Marylebone Road, London, N.W., Analytical Chemist.
- Bower, H., Gray's Ferry Road, and Twenty-ninth Street, Philadelphia, Pa., U.S.A., Chemical Manufacturer.
- Bowes, Harry, 53, Moss Bank, Higher Crumpsall, Manchester, Analytical Chemist.
- Bowing, Jno., Fuel Works, Tilbury, Essex, Manufacturing Chemist.
- Bowley, Jos. John, Wellington Works, Battersea Bridge, London, S.W., Chemical Manufacturer.
- Bowman, Dr. F. H., Mayfield, Knutsford, Cheshire, Chemical Manufacturer.
- Bowman, Jas. H., Canada Chemical Manufacturing Co., London, Ont., Canada, Professor of Chemistry.
- Bowman, R., Elabouga, Government of Viatka, Russia, Chemical Director of Works.
- Bowman, Wm. P., 7, White Horse Street, Leeds, Wholesale Druggist.
- Bowrey, J. J., Kingston, Jamaica, West Indies; and (subs.) 62, Penshurst Road, South Hackney, N.E., Analytical Chemist.
- Boyce, Frank, c/o Goodall, Backhouse, and Co., White Horse Street, Leeds, Technical Chemist.
- Boyd, Pythagoras, 72, Marshall Street, North Adams, Mass., U.S.A., Print Works Superintendent.
- Boyd, W., Tharsis Co.'s Works, Hebburn-on-Tyne, Chemical Engineer.
- Boyd, W., Thornton, R.S.O., Fifeshire, N.B., Technical Chemist.
- Boyden, F. D., 90, Waterloo Road, Manchester, Calico Printer's Assistant.
- Bradburn, J. A., 1816, West Genesee Street, Syracuse, N.Y., U.S.A., Chemical Engineer (Ammonia Soda Manufacture).
- Bradbury, A., Queen Buildings, 11, Dale Street, Liverpool, Chemical Broker.
- Bradford, Henry, 21, Kensington Mansions, Earl's Court, S.W.
- Bradley, Edw. F., The Star Brush Co., Ltd., Eden Grove, Holloway, N., Engineer.
- Braithwaite, Isaac, Kendal, Westmoreland, Drysalter.
- Bramham, W., 115, Bow Road, London, E., Chemical Engineer.
- Bramwell, Major E., Ethersall, Huyton, near Liverpool, Chemical Manufacturer.
- Bramwell, Sir F., Bart., F.R.S., 5, Great George Street, Westminster, London, S.W., Civil Engineer.
- Bramwell, G. H., Cowley Hill, St. Helens, Lancashire, Alkali Manufacturer.
- Bramwell, Samuel, 18, St. Ann's Street, Manchester, Oil and Chemical Broker.
- Branson, F. W., Wynnholme, Far Headingley, Leeds, Pharmaceutical Chemist.
- Bray, Daniel, Broadmoor Chemical Works, Cinderford, Gloucestershire, Chemist and Managing Partner.
- Breckon, J. R., 53, John Street, Sunderland, Merchant.
- Breen, George, c/o Irvine Chemical Co., Ltd., 204, St. Vincent Street, Glasgow, Chemical Works Manager.
- Breffitt, Wm., Glasshoughton, Castleford, Yorks, Glass Manufacturer.
- Breneman, Dr. A. A., 97, Water Street, New York, U.S.A., Analytical Chemist.
- Bressey, Edw., 209, Romford Road, Stratford, E., Gold and Silver Refiner.
- Breyer, Theodor, 105, Main Street, Peoria, Ill., U.S.A., Chemist (American Glucose Co.).
- Briant, L., 24, Holborn Viaduct, London, E.C., Analytical Chemist.
- Brierley, J. T., 249, Bolton Road, Chorley, Lancashire, Analytical Chemist.
- Briggs, J. Burnett, Vauxhall Soap Works, 6, Blackstock Street, Liverpool, Soap Manufacturer.
- Briggs, J. F., c/o Messrs. Parry and Co., Madras, India, Sugar Works Chemist.
- Briggs, T. Lynton, 357, Madison Street, Brooklyn, New York, U.S.A., Technical Chemist.
- Briggs, W., 4, Erskine Terrace, Dundee, Manufacturing Chemist.
- Brindley, G. F., c/o The Aluminium Co., Ltd., Oldbury, Birmingham, Chemical Engineer.
- Bristed, John (Journals); c/o Messrs. Kemp and Co., Bombay, India; and (subs.) H. B. Sleeman, 84, Leadenhall Street, E.C., Manager.
- Bristow, G. W., Worcester House, 35, Eastcheap, London, E.C., Chemical Manager.
- Broadbent, H., c/o Goodall, Backhouse, & Co., Sovereign Street, Leeds, Chemist.
- Broek, Arthur, Messrs. C. T. Broek & Co., South Norwood, S.E., Firework Manufacturer.
- Broek, J., 17, Abercromby Square, Liverpool, Chairman of United Alkali Co., Ltd.
- Brook, G. Bernard, 27, Wostenholm Road, Sheffield, Analytical Chemist.
- Brooke, Edw., Oakley House, Edgerton, Huddersfield, Fireclay Manufacturer.
- Brooke, Wilton, Ashville, Stainfoot, Barnsley, Yorks, Manufacturing Chemist.
- Brookes, E. A., 31, Bamford Road, Didsbury, near Manchester, Analytical Chemist.
- Brookman, Fred. W., 228, Entwisle Road, Rochdale, Manure Works Manager.
- Broome, F. J., Holloway, near Matlock, Derbyshire, Assayer.
- Brothers, H. E., Victoria Institute, Tunstall, Stoke-on-Trent, Analyst.
- Brotherton, E. A., Commercial Buildings, Leeds, Ammonia Distiller.
- Brown, Prof. A. Crum, F.R.S., 8, Belgrave Crescent, Edinburgh, Professor of Chemistry.
- Brown, Caesar R., Anglo-Continental Guano Works Victoria Docks, E., Works Foreman.
- Brown, D., 93, Abbey Hill, Edinburgh, Chemical Manufacturer.
- Brown, D., Donaghmore, Tyrone, Ireland, Soap Manufacturer.

- Brown, Edw., Russian Steam Oil Mills, 22, Kourlandsky Street, St. Petersburg, Analytical Chemist.
- Brown, F. W., 13, Elgin Avenue, Maida Hill, W.
- Brown, G. E., Great Western Railway Laboratory, Swindon, Chemist.
- Brown, H., Cannon Brewery, Watford, Herts, Brewing Chemist.
- Brown, Horace T., F.R.S., 52, Neven Square, Kensington, S.W., Brewing Chemist.
- Brown, Dr. J. Campbell, 8, Abercromby Square, Liverpool, Professor of Chemistry.
- Brown, J. Henry, c/o Bowman, Thompson, & Co., Ltd., Northwich, Technical Chemist.
- Brown, Oliphant A., Lennoxmill, Lennoxtown, N.B., Print-works Manager.
- Brown, Reginald B., 18, Warwick Place, Leeds, Dyer's Chemist.
- Brown, Robt., The Firs, Hartford, Northwich, Engineer.
- Brown, R. J., Technical School, Stockport, Principal.
- Brown, T., The Chemical Works, King's Lynn, Chemical Manufacturer.
- Brown, W., Aitcheson, Tudor Oil Works, Port Elizabeth, Cape Colony, South Africa, Oil Works Manager.
- Brown, Walter, c/o Jas. H. Dennis and Co., Widnes, Assayer.
- Brown, Wm., Pioneer Sugar Estate, Lower Burdekin, Townsville, Queensland, Chemist.
- Browning, W., Broad Oak, Accrington, Calico Printer.
- Broxap, Walter, Newton Chemical Works, Hyde, Manchester, Analytical Chemist.
- Bruce, Jas., The Irish Distillery, Connswater, Belfast, Ireland, Distiller.
- Bruckmann, G. T., 192, 18th Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
- Brunner, H., Holly Mount, Tarbock Road, Huyton, near Liverpool, Chemical Manufacturer.
- Brunner, H. Bertram, Warrington Old Hall, Northwich, Chemist and Electrician.
- Brunner, J. F. L., Warrington Old Hall, Northwich, Cheshire, Chemical Manufacturer.
- Brunner, Sir J. T., Bart., M.P., Druid's Cross, Wavertree, Liverpool, Chemical Manufacturer.
- Brunton, J. Dixon, Wire Mill, Musselburgh, N.B., Wire Manufacturer.
- Bryan, A. Hugh, Indianapolis High School No. 1, Indianapolis, Ind., U.S.A., Teacher of Chemistry.
- Bryce, John Annan, Messrs. Wallace Bros., 8, Austin Friars, London, E.C., Merchant.
- Bryce, Thos., Tharsis Mines, Huelva, Spain, Chemist.
- Bryce-Smith, N. J., Oakfield, Barrow, Whalley, near Blackburn, Calico Printer.
- Buehan, Alex., Maude Cottage, Pellatt Grove, Wood Green, N., Chemist.
- Buchanan, D. G., Mount Vernon House, Glasgow, Analyst.
- Buchanan, Jas., jun., Caledonia Foundry, Brasenose Road, Liverpool, Engineer.
- Buchanan, Joshua, Buffelsdoorn, via Potchefstroom, S.A.R., Analytical Chemist.
- Budden, E. R., 11, Farnival Street, Holborn, E.C., Consulting Chemist.
- Bull, Johannes C., Erith, Kent, Chemical Engineer.
- Bullock, J. L., 3, Hanover Street, Hanover Square, London, W., Manufacturing Chemist.
- Bunby, H., c/o Millon and Askam Hematite Iron Co., Ltd., Askam-in-Furness, Lancashire, Ironworks Manager.
- Bunker, H. E., 1, Deanley Terrace, St. Mary's Road, Newton Heath, Manchester, Technical Chemist.
- Bunting, W. Lightfoot, c/o F. W. Ashton & Co., Hyde, near Manchester, Calico Printer.
- Barbridge, Jas., India-rubber Mills, Tottenham, N., India-rubber Manufacturer.
- Burdekin, G., jun., Sutton Lodge Works, St. Helens, Chemical Works Manager.
- Burger, Dr. J., 1, Birch Avenue, Talbot Road, Old Trafford, Manchester, Technical Chemist.
- Burgess, Geo., Golding Davis Works, Widnes, Chemist.
- Burgess, Herbert, c/o Bexington and Sons, Neckinger Mills, Bermoudsey, S.E.; and (Journals) 11, Pendrell Road, Brockley, S.E., Dyer and Chemist.
- Burgess, Herb. E., 16, Bloomsbury Street, London, W.C., Chemist.
- Burgess, Wm. T., Beech Road, Reigate Hill, Surrey, Analytical Chemist.
- Burghardt, Dr. C. A., Fern Cottage, Alderley Edge, Cheshire, Consulting Chemist.
- Burnard, R., Plymouth Chemical Works, Plymouth, Chemical Manufacturer.
- Burnet, Henry K., North Brook Vitriol Works, Bradford, Yorks, Vitriol Maker.
- Burnham, J. C., Gunpowder Factory, Kirkee, near Poona, India, Analytical Chemist.
- Burn-Murdoch, J. V., Elmtree House, Pembroke, South Wales, Assayer.
- Burrell, B. A., 5, Mount Preston, Leeds, Analytical Chemist.
- Burrough, Horace, jun., 1130, Lafayette Avenue, Baltimore, Md., U.S.A., Technical Chemist.
- Burrows, Edw., Belle Vue Road, Low Fell, Gateshead-on-Tyne, Alkali Works Manager.
- Burton, F., 2, Green Street, Bethnal Green, E., Colour Manufacturer.
- Burton, Wm., Clifton Junction, near Manchester, Potter's Chemist.
- Bury, J. H., Church Chemical Works, near Accrington, Chemical Manufacturer.
- Bush, R. A., 20, Artillery Lane, London, E.C., Chemical Manufacturer.
- Bush, Baron W. de, 20, Artillery Lane, London, E.C., Chemical Manufacturer.
- Butler, Paul, Lowell, Mass., U.S.A., Ammunition Manufacturer.
- Butler, Samuel, Compton, Wolverhampton, Brewer.
- Butler, W. W., The Cedars, Duchess Road, Edgbaston, Birmingham, Brewer.
- Butterfield, J. C., 13, Victoria Street, Westminster, S.W., Analytical Chemist.
- Butterfield, W. J. A., Beekton, E., Analytical Chemist.
- Butt, E. N., 77, Hamilton Terrace, Maida Vale, W., Pharmaceutical Chemist.
- Buttfield, Horace V., 13, Wellington Road, Bush Hill Park, Enfield, N., Chemical Demonstrator.
- Byard, A. G., c/o Bart, Boulton, and Heywood, Apartado 8, Bilbao, Spain, Technical Chemist.
- Byrom, T. H., Laboratory, Wigan Coal and Iron Co., Wigan, Analytical Chemist.
- Bythway, M., 43, Lloyd Street, Albert Street, Manchester, Drysalter.

C

- Cabot, Godfrey L., 82, Water Street, Boston, Mass., U.S.A., Chemist.
- Cadett, Jas., Ashted, Surrey, Photographic Dry Plate Maker.
- Caines, G. S. A., 7, Rochester Terrace, Camden Road, London, N.W., Analytical Chemist.
- Caldecott, Arthur, Box 574, Johannesburg, S.A.R., Metallurgist.
- Calderwood, J., Gowanlea, Spence Park, Wandsworth, S.W.; and Price's Patent Candle Co., Battersea, Candle Manufacturer.
- Caldwell, Wm., Murray Street, Paisley, N.B., Drysalter.
- Catkin, Wm. S., Johnsonburg Quay P.O., Pa., U.S.A., Paper Pulp Works Chemist.
- Cambier, Jacob, c/o C. F. and I. Co., Pueblo, Colo., U.S.A., Chemist.
- Cameron, Alex., Agricultural Laboratory, 4, Lombard Court, E.C., Analytical Chemist.
- Cameron, Jas., c/o The British Explosives Syndicate, Ltd., Pitsea, Essex, Chemist.
- Cameron, Peter, Bath Bridge Colour Works, Bristol, Colour Works Manager.
- Cammack, J., 8, Salisbury Street, St. Helens, Technical Chemist.
- Campbell, Andrew, c/o Barmah Oil Co., Ltd., Rangoon, Barmah, Analytical Chemist.
- Campbell, Archibald, 42, Whittaker Road, Upton Park, E., Technical Chemist.

- Campbell, Colin M., c/o Long & Robertson, Habana, Mackay, Queensland, Colour Chemist.
- Campbell, John, 118, Warren Street, New York City, U.S.A., Dye Manufacturer.
- Campbell, Jno. D., 10, St. Mary Axe, London, E.C., Oil Merchant.
- Campbell, Peter, c/o The Nairn Linoleum Co., P.O. Box 32, Newark, N.J., U.S.A., Manager.
- Candlish, J. J., Bottle Works, Seaham Harbour, co. Durham, Glass Manufacturer.
- Cannon, J. C., 70, Ham Park Road, Forest Gate, E., Analyst.
- Cannon, M., Beaufoy's Chemical Works, Lavender Hill, London, S.W., Vinegar Works Manager.
- Canziani, Enrico, 3, Palace Green, Kensington, W., Civil Engineer.
- Carden, Albert J., Lea Valley Distillery, Warton Road, Stratford, E., Distiller.
- Carey, Arthur, Browside, Gateacre, near Liverpool, Chemist.
- Carey, E., Browside, Gateacre, near Liverpool, Chemical Manufacturer.
- Cargey, W. E., c/o Selopis and Co., 31, Via Aosta, Torino, Italy, Works Chemist.
- Carlile, T., 23, West Nile Street, Glasgow, Chemical Manufacturer.
- Carlsson, Hugo, c/o The Johnson Co., Lorain, Ohio, U.S.A., Analytical Chemist.
- Carmichael, H., 12, Post Office Square, Boston, Mass., U.S.A., Analytical Chemist.
- Carmody, Prof. Patrick, Government Laboratory, Port of Spain, Trinidad, Analytical Chemist.
- Caro, Dr. H., Mannheim, Germany, Technical Chemist.
- Carpenter, C. C., Gas Works, Bridge Foot, Vauxhall, S.E., Civil Engineer.
- Carpenter, H. S., Beckington House, Weighton Road, Anerley, S.E., Insurance Broker.
- Carpenter, R. F., Prestwich, Greencroft Gardens, West Hampstead, N.W., Alkali Works Inspector.
- Carruthers, J. G., Burnbrae House, Milngavie, N.B., Dye-works Manager.
- Carswell, Thos. R., 19, Cheetham Place, Cheetham Hill, Manchester, Analyst and Teacher of Chemistry.
- Carteighe, M., 180, New Bond Street, London, W., Pharmaceutical Chemist.
- Carter, Stewart E., P.O. Box 221, North Adams, Mass., U.S.A., Chemist.
- Carter, W. C., 19, Short Strand, Belfast, Ireland, Analytical Chemist.
- Carulla, F. J. R., 84, Argyll Terrace, Derby, Chemical Manufacturer.
- Carulla, F. M., Apartado 689, Buenos Ayres, Argentina; and (Journals) 84, Argyll Terrace, Derby, Gunpowder Manufacturer.
- Case, W. T., 7, Cedar Street, New York, U.S.A., Chemist.
- Castner, Hamilton Y., c/o The Aluminium Co., Ltd., Oldbury, Birmingham, Chemical Engineer.
- Catlin, Chas. A., 133, Hope Street, Providence, R.I., U.S.A., Chemist (Rumford Chemical Works).
- Caven, Robt. M., University College, Nottingham, Lecturer in Chemistry.
- Cawley, G., 29, Great George Street, Westminster, S.W., Chemical Engineer.
- Cawley, J., 278, Passaic Street, Newark, N.J., U.S.A., Analytical Chemist.
- Chadwick, Walter M., 24, West 3rd Street, Bayonne, N.J., U.S.A., Chemical Works Manager.
- Chaloner, G., 30, Weston Park, Crouch End, N., Chemical Lecturer.
- Chaloner, G. W., Niagara Works, Eagle Wharf Road, London, N., Chemical Manager.
- Chance, A. M., Lawnside, Edgbaston, Birmingham, Chemical Manufacturer.
- Chance, J. F., 51, Prince's Gate, London, S.W., Chemical Manufacturer.
- Chandler, Dr. C. F., School of Mines, Columbia College, New York, Professor of Chemistry.
- Chaplin, Dr. Edw. M., 60, Westgate, Wakefield, Yorks, Analytical Chemist.
- Chapman, Alf. C., East India Chambers, 23, Leadenhall Street, E.C., Analytical Chemist.
- Chapman, S., 36, Mark Lane, E.C., Chemical Manufacturer.
- Charlier, Andrew, 107, Breadalbane Terrace, Hill Street, Glasgow, General Manager and Chemist.
- Chase, R. L., 155, East Main Street, North Adams, Mass., U.S.A., Professor of Chemistry.
- Chatard, Dr. T. M., 1714, Rhode Island Avenue, Washington, D.C., U.S.A., Chemical Engineer.
- Cheney, J. P., c/o Cheney Bros., South Manchester, Conn., U.S.A., Silk Manufacturer's Chemist.
- Cheyne, A. M., c/o Messrs. Burgoyne, 16, Coleman St., E.C., Analytical Chemist.
- Cholerton, A. F., Lyndum House, Lincoln Street, Leicester, Manufacturing Chemist.
- Chope, J. A., The Laboratory, Somerset House, London, W.C., Assistant Chemist.
- Chorley, Jno. C., Lodge Lane, Bewsey, Warrington, Analytical Chemist.
- Christie, J., Levenfield, Alexandria, N.B., Dyer and Printer.
- Christy, Thos., Malvern House, Sydenham, S.E.; and 25, Lime Street, London, E.C., Chemical Botanist.
- Chrystal, W. J., Shawfield Works, Rutherglen, near Glasgow, Chemical Manufacturer.
- Church, Professor A. H., F.R.S., Shelsley, Kew, Surrey, Professor of Chemistry in the Royal Academy.
- Church, Elihu D., jun., Trenton, Wayne Co., Mich., U.S.A., Soda Manufacturer.
- Clanahan, H. C., 88, King Street, Manchester, Chemical Merchant.
- Clapp, Ralph R., c/o Standard Ammonia Co., Ltd., Iceland Wharf, Old Ford, E., Ammonia Works Manager.
- Clapperton, J., jun., 25, Queen Square, Regent Park, Glasgow, Analytical Chemist.
- Clark, Edwin S., Oak Alyn, Gwersyllt, near Wrexham Colliery Proprietor.
- Clark, Dr. Franklin S., 527, Madison Avenue, New York City, U.S.A.; and (Journals) Southern Chemical Works, Wilmington, N.C., U.S.A., Manufacturing Chemist.
- Clark, Dr. J., 138, Bath Street, Glasgow, Analytical Chemist.
- Clark, R. Ingham, 3, Albert Hall Mansions, Kensington Gore, W., Manufacturer.
- Clarke, Arthur, St. Ann's Hill Factory, Nottingham, Bleacher and Dyer.
- Clarke, C. Goddard, Ingleside, Elm Grove, Peckham, S.E., Drysalter.
- Clarke, E. Lloyd, Brooklands, Cuddington, Northwich, Merchant.
- Claudet, A. C., 6, Coleman Street, London, E.C.; and (Journals to) 9, Daleham Gardens, Hampstead, N.W., Metallurgist.
- Claudet, F. G., 6, Coleman Street, E.C.; and (Journals) 3, Manor Rise Terrace, Dulwich, S.E., Assayer and Metallurgist.
- Claus, C., c/o Francis Arding, 5, Jeffrey Square, London, E.C., Chemical Engineer.
- Claus, Carl F., jnn., 94, Grove Park Terrace, Chiswick, W., Electrolytic Chemist.
- Claus, Wm. H., 24, Egerton Road, Fallowfield, Manchester, Manufacturing Chemist.
- Clayton, E. G., Chemical Laboratory, 32, Holborn Viaduct, London, E.C., Analytical Chemist.
- Clayton, Dr. G. Christopher, Standfield, Wavertree, Liverpool.
- Clayton, J. W., Bentfield, Alma Road, Aigburth, Liverpool, Pharmaceutical Chemist.
- Clayton, Robt. H., 61, Higher Ardwick, Manchester, Chemist.
- Clementson, H., c/o Columbus Distilling Co., 80, Pire Street, New York, U.S.A., Distiller.
- Clemes, J. H., Cheriton, Chelston, Torquay.
- Cleminshaw, E., Alkali Works, Oldbury, near Birmingham, Technical Chemist.
- Clemons, G. H., Cudbear Street, Hunslet Road, Leeds, Dyeware Manufacturer.
- Clerk, Dugald, Driffold Villa, Sutton Coldfield, near Birmingham, Engineer.

- Cliff, J., Nisbet Hall, Fulneck, Leeds, Firebrick Maker.
 Cliff, Stephen, Wortley, near Leeds, Firebrick Maker.
 Clifton, C. D., Royal Oak Brewery, Stockport, Brewer.
 Cloud, T. C., Wallaroo Smelting Works, Wallaroo, South Australia, Metallurgist and Manager.
 Clowes, Dr. F., University College, Nottingham, Professor of Chemistry.
 Clowes, G. A., Needham Market, Suffolk, Brewer and Maltster.
 Clutton, J. H., Goring Villas, Barry Port, R.S.O., Carmarthenshire, Assayer.
 Coats, Jno. T., 91, Broughton Street, Edinburgh, Manufacturing Chemist.
 Cobb, Jno. W., Farnley Iron Co., near Leeds, Ironworks Chemist.
 Coblenz, Dr. Virgil, College of Pharmacy, 115, West 68th Street, New York, U.S.A., Chemical Lecturer.
 Cochran, Chas., Green Royde, Pedmore, near Stourbridge, Ironmaster.
 Cochrane, Jno., Spring Field, New Mills, near Stockport, Printworks.
 Coghill, P. de G., Borax Works, Old Swan, Liverpool, Technical Chemist.
 Cogswell, W. B., Syracuse, New York, U.S.A., Chemical Engineer.
 Cohen, Dr. J., Yorkshire College, Leeds, Analytical Chemist.
 Coker, Ernest G., H.M. Patent Office, Chancery Lane, W.C., Examiner of Patents.
 Colby, Albert L., c/o Bethlehem Iron Co., South Bethlehem, Pa., U.S.A., Metallurgical Engineer.
 Colby, W. H., Carreg-wen, Aberystwith, Analytical Chemist.
 Colechester, G. H., Burwell, near Cambridge, Manure Manufacturer.
 Colefax, Dr. Arthur, (Journals) 26, Ashgrove, Bradford, Yorks, and (poetics and subs.) 14, Chester Terrace, London, S.W., Barrister-at-Law.
 Coleman, Jas. B., South-Western Polytechnic, Manresa Road, Chelsea, S.W., Analytical Chemist.
 Coleman, W. H., 9, Lloyd Road, East Ham, Essex, Tar Works Chemist.
 Collens, E., Vinegar Works, Stourport, Worcestershire, Vinegar Works Manager.
 Collett, J. M., Guy's Cliff, Wotton, Gloucester, Chemical Manufacturer.
 Collin, Dr. C. A., Ferguslie Threadworks, Paisley, N.B., Textile Chemist.
 Collins, H. S., c/o Davy, Yates, and Hicks, 64, Park Street, Southwark, S.E., Analytical Chemist.
 Collins, J. H., 14-15, Broad Street Avenue, London, E.C., Technical Chemist.
 Collins, W., Hepworth, Bradford Buildings, Bolton, Lancashire, Analytical Chemist.
 Collings, C. S. A., c/o Mrs. Goulding, 70, Elm Row, Leith Walk, Edinburgh, Chemist.
 Colman, Dr. H. G., 23, Stirling Road, Edgbaston, Birmingham, Analytical Chemist.
 Colquhoun, D., Maulesbank, Carnoustie, N.B., Chemical Works Manager.
 Colquhoun, Lewis, c/o British and Colonial Explosives Co., Ltd., Perranporth, R.S.O., Cornwall, Analytical Chemist.
 Colquhoun, W., c/o Francis Morton and Co., Ltd., Garston, Liverpool, Engineer.
 Colson, A., Gas Office, Millstone Lane, Leicester, Gas Engineer.
 Comer, H., 1, Broadway, New York, U.S.A., Creosote Works Manager.
 Connor, C. C., M.P., 4, Queen's Elms, Belfast, Ireland, Chemist.
 Conradson, Pontus H., Great Northern Railroad, St. Paul, Minn., U.S.A., Analytical Chemist.
 Conroy, Dr. Jas. T., Woodstock, New Brighton, Cheshire, Chemist.
 Constable, W. H., Hale Bank, Widnes, Lancashire, Analytical Chemist.
 Coope, J. Charles, 19, Freeland Road, Ealing, W., Civil Engineer.
 Cook, E. M., Room 40, 76, Park Place, New York, U.S.A., Chemical Manufacturer.
 Cook, E. Rider, East London Soap Works, Bow, London, E., Soap Manufacturer.
 Cook, H. J., East London Soap Works, Bow, London, E., Soap Manufacturer.
 Cook, Jas. Williams, London and Provincial Dyeworks, Hackney Wick, N.E., Dyer.
 Cook, Jno. J., Atlas Foundry, St. Helens, Lancashire, Iron-founder.
 Cook, Wm. Martyn, 29, Highbury Hill, London, N., Analytical Chemist.
 Cooke, Arthur W., c/o Goodlet and Smith, Ltd., Granville, near Sydney, N.S.W., Analytical Chemist.
 Cookson, Jas. H., Stanley, near Wakefield, Alum Manufacturer.
 Cookson, N. T., Newcastle-on-Tyne, White Lead Manufacturer.
 Coomber, Thos., 40, Clarendon Road, Redland, Bristol, Chemical Lecturer.
 Cooper, A., North-Eastern Steel Co., Middlesbrough-on-Tees; and (Journals) Erdely, Middlesbrough, Steel Works Manager.
 Cooper, Bertwin, Derby Oxide and Colour Co., Ltd., Rugeley, Staffordshire, Colour Manufacturer.
 Cooper, H. P., 2, New North Road, Hoxton, N., Manufacturing Chemist.
 Cooper, Harry J., Drinagh, Wexford, Ireland, Cement Manufacturer.
 Cooper, Walter J., c/o South Wales Cement Co., Penarth, Cardiff, Cement Works Manager.
 Corbould, Wm. H., Hannan's Reward Gold Mine, Kalgoorlie, West Australia, Manager.
 Corcoran, Bryan, 31, Mark Lane, London, E.C., Chemical Engineer.
 Corder-James, J. H., Finsbury House, Blomfield Street, London, E.C., Mining Engineer.
 Cornett, Jas. P., Ford Paper Works, Hylton, near Sunderland, Paper Maker.
 Cornish, Vaughan, 102, Edgware Road, London, W., Chemical Lecturer.
 Corpataux, J., 6, Cliff Villas, Toller Lane, Bradford, Yorks, Technical Chemist.
 Corrie, David, c/o Nobel's Explosives Co., Ltd., Polmont Station, N.B., Technical Chemist.
 Coste, J. H., 40, Craven Street, W.C.; and (Journals) 206, Amhurst Road, Hackney, E., Analytical Chemist.
 Cotterill, Thos., The Poplars, West Bromwich, Chemical Agent.
 Cotton, W. F., Hollywood Roebuck, Co. Dublin, Gas Works Manager.
 Court, Heywood, 67, Surrey Street, Sheffield, Analytical Chemist.
 Cousins, W. J., 11 and 12, Southampton Buildings, Chancery Lane, W.C., Consulting Chemist and Director.
 Cowan, W. J., 77, Trinity Road, Wood Green, N., Fine Colour Manufacturer.
 Coward, Percy, 68, Brundrett's Road, Chorlton-cum-Mardy, Manchester, Chemist.
 Cowburn, W. H., Sutton House, Ashley Road, Bowdon, Cheshire, Chemical Merchant.
 Cownley, A. J., 13, Fenchurch Avenue, London, E.C., Analytical Chemist.
 Cowper, C. E., 6, Great George Street, Westminster, S.W., Civil Engineer.
 Cowper-Coles, Sherard Osborn, 16, Adam Street, Manchester, Square, W., Metallurgical Manufacturer.
 Cox, Robt. M.P., Messrs. J. and G. Cox, Gorgie, Edinburgh, Gelatine Manufacturer.
 Crabb, W., Border Counties Chemical and Manure Works, Silloth, Cumberland, Chemical Manufacturer.
 Craig, G., 9, Hampden Terrace, Mount Florida, Glasgow, Technical Chemist.
 Craig, Thos. J., c/o Messrs. Peter Spence and Sons, Manchester Alum Works, Manchester, Chemist.
 Crane, Wm., 99, Seiborne Street, Attercliffe, Sheffield, Analytical Chemist.
 Craven, Chas. E., Hawthorne Cottage, White Cote Hill, Bramley, near Leeds, Dyer.

Craven, Jno., jun., Smedley Lodge, Cheetham, Manchester, Chemist.

Craw, John, 15, Cadogan Street, Glasgow, Drysalter.

Crawford, D., Langdale's Chemical Manure Co., Lim., Mashroom, Newcastle-on-Tyne, Manager.

Crawford, D., The Elms, Handforth, Cheshire, Dyer and Printer.

Crawley, Arthur H., Schladerm a/d Sieg, Rhenish Prussia, Analytical Chemist.

Crawshaw, E., 25, Tollington Park, London, N., Dye Merchant.

Cremer, John H., 24, Superior Street, Cleveland, Ohio, U.S.A., Chemist and Metallurgist.

Cresswell, C. G., Ermyngarth, Ashted, Surrey; and 9, Bridge Street, Westminster, S.W., Chemist.

Cresswell, C. N., 1, Ilare Court, Temple, E.C., Barrister-at-Law.

Crichton, Donald G. (Journals), Nundle, via Tamworth, New South Wales; (subs.) Logan Bank, Cupar Fife, N.B., Analytical Chemist.

Criper, Wm. R., Cossipore Chemical Works, Cossipore, Calcutta, India, Manufacturing Chemist.

Crippin, Wm., The Hollies, Eccles, Manchester, Dyer.

Critchley, C. A., Victoria Works, St. Helens, Lancashire, Colour Manufacturer.

Crompton, Percy R., Dearden's House, Bury, Lancashire, Paper Maker.

Cronquist, Prof. A., Werner, Royal Wharf, Skeppsholmen, Stockholm, Sweden, Technical Chemist.

Crookes, W., F.R.S., 7, Kensington Park Gardens, Notting Hill, London, W., Analytical Chemist.

Crosfield, A. L., Casino Ingles, Minas de Rio Tinto, Huelva, Spain, Analytical Chemist and Assayer.

Cross, C. F., 4, New Court, Lincoln's Inn, London, W.C., Analytical Chemist.

Crossley, Dr. Arthur W., Chemical Laboratory, St. Thomas' Hospital, London, S.E., Organic Chemist.

Crossley, Atkinson, The Scarlet Ferrie Oxide Co., Talywain, near Pontypool, Chemist.

Crossman, Tom, Albion Brewery, Coldhurst Street, Oldham, Brewing Chemist.

Crow, Dr. J. K., 23, Vanburgh Hill, Blackheath, S.E., Technical Chemist.

Crow, Henry W., Abbey Creek Wharf, West Ham, E., Tar Distiller.

Crowder, W., 271, Evering Road, Upper Clapton, London, N., Manure Works Manager.

Crowthier, Edw., Woodland Dyeworks, Headingley, Leeds, Dyer.

Crowthier, Horace W., 21, Beeches Road, West Bromwich, Technical Chemist.

Crowthier, W. M., Field House, Gomersal, near Leeds, Manufacturing Chemist.

Crumbie, W. D., 146, Washington Street, East Orange, N.J., U.S.A., Analytical Chemist.

Cullen, Wm., Ardeer Terrace, Stevenston, Ayrshire, N.B., Chemist.

Cunniog, James, jun., Chemical Works, Yarraville, Melbourne, Australia, Manure Manufacturer.

Cunniog, T. A., Craiglea, Causewayhead, near Stirling, N.B., Cotton Dyer.

Cunliffe, E. T., The Parsonage, Handforth, near Manchester.

Cunliffe, Jos., Kern Mill, Whittle-le-Woods, near Chorley, Lancashire, Calico Printer.

Cunningham, Edw., Milton, Mass., U.S.A., Chemical Engineer.

Cunningham, H. D., 24, Rood Lane, Loudon, E.C., Metallurgical Manager.

Curphey, W. S., 15, Bute Mansions, Hillhead, Glasgow, Alkali Works Inspector.

Currie, Stanley C. C., 45, Broadway, New York, U.S.A., Electrical Engineer.

Curry, W. A., Giltbrook Chemical Works, Awsworth, Notts, Manager.

Curtmau, Prof. Chas. O., 3718, North 9th Street, St. Louis, Mo., U.S.A., Professor of Chemistry.

Cushman, Allerton S., Washington University, St. Louis, Mo., U.S.A., Instructor in Chemistry.

Cuthbert, R. M., 27a, Ashley Place, London, S.W., Russia Broker.

Cuthbertson, Sir J. N., 29, Bath Street, Glasgow, Chemical Broker.

Cuthbertson, William, 34, Marchmont Crescent, Edinburgh, Chemical Manufacturer.

D

Dacie, J. C., Soap Works, Putney, London, S.W., Soap Manufacturer.

Dale, Jas., 182, Lordship Road, Stoke Newington, N., Coppersmith.

Dale, R. S., 1, Chester Terrace, Chester Road, Manchester, Chemical Manufacturer.

Daniell, Louis C. (Journals), Royal Standard Brewery, Tamworth, New South Wales; and (subs.) c/o W. T. Allen & Co., 132, Queen Victoria Street, London, E.C., Brewer.

Darby, J. H., Pen-y-Garth, near Wrexham, Ironmaster.

Darling, G. A., c/o Robinson Gold Mining Co., Box 1021, Johannesburg, S.A.R., Metallurgical Chemist.

Darling, W. H., 126, Oxford Street, Manchester, Analytical Chemist.

Davenport, Dr. B. F., 161, Tremont Street, Boston, Mass., U.S.A., Consulting, Sanitary, and Toxicological Chemist.

Davidson, J. E., 40, Percy Gardens, Tynemouth, Chemical Manufacturer.

Davidson, Richard, 40, Lilybank Road, Dundee, Oil Merchant's Clerk.

Davidson, R. H., c/o United Alkali Co., Ltd., Golding Davis Works, Widnes, Analytical Chemist.

Davies, G. W., 8, Spring Hill, Stockport, Chemical Lecturer.

Davies, Llewellyn J., 8, Wordsworth Avenue, Cardiff, Assistant Analyst.

Davies, M. Lloyd, Mayfield, Norman Road, Runcorn, Alkali Works Manager.

Davies, W. E., c/o Messrs. Easton, Anderson, and Goolden, Lim., Erith, Kent, Secretary.

Davis, A. R., Lynton, Wellington Road North, Stockport, Analytical Chemist.

Davis, Chas., 3, Leitrim Terrace, High Street, East Ham, E., Analytical Chemist.

Davis, Fred., 26-28, Newington Causeway, Loudon, S.E., Analytical and Consulting Chemist.

Davis, George E., Sandilands, Knutsford, Cheshire, Chemical Engineer.

Davis, Herbert J., 45, Wall Street, New York, U.S.A., Merchant.

Davis, H. W., Government Laboratory, Somerset House, W.C., Analytical Chemist.

Davis, T. Sebastian, 199, South Lambeth Road, London, S.E., Vinegar Works Chemist.

Davis, W. Walley, jun., c/o Crozer Iron Co., Roanoke, Va., U.S.A., Analytical Chemist.

Dawson, B., York House, Malvern Link, Worcestershire, Engineer.

Dawson, C. A., Holly Bank, Frodsham, Cheshire, Technical Chemist.

Dawson, Geo., Reddish Chemical Works, near Stockport, Technical Chemist.

Dawson, Jas., 27, St. Vincent Place, Glasgow, Drysalter.

Dawson, W. Haywood, British Alizarin Co., Limited, Silvertown, Victoria Dock, E.; and (Journals), 131, Herbert Road, Woolwich, S.E., Technical Chemist.

Deacon, H. W., Appletou House, Widnes, Alkali Manufacturer.

Deakin, E. C., Ryecroft House, Belmont, near Bolton, Dyer.

Deakin, H., Ryecroft Dyeworks, Belmont, near Bolton, Dyer.

Dearden, Thos., 12, Heywood Street, Bury, Lancashire, Technical Chemist.

Deaville, B., Hyson Green Works, Nottingham, Manufacturing Chemist.

De Clerck, Maurice, Heule-lez-Courtrai, Belgium.

- Deering, W. H., Chemical Department, Royal Arsenal, Woolwich, S.E.; and (Journals) 9, Harvey Villas, Hervey Road, Blackheath, S.E., Analytical Chemist.
- Delahaye, Philibert, 65, Rue de Provence, Paris, Gas Engineer.
- De Lessing, G. C., 589, Lexington Avenue, New York, U.S.A., Manufacturing Chemist.
- Dempsey, Geo. C., 165, Market Street, Lowell, Mass., U.S.A., Chemist.
- Demuth, Dr. L., Wharfside, Church Road, Edgbaston, Birmingham, Tar Distiller.
- Denison, Joseph R., 1, Park View Terrace, Manningham, Bradford, Analytical Chemist.
- Derriek, Wm. H., c/o The Pahang Corporation Ltd., Kuantan, via Singapore, S.S., Mining Engineer.
- De Velling, F. W., Higher Grade Board School, The Boulevard, Hull, Head Master and Science Lecturer.
- Devey, A. C., c/o La Société Hermite, 4, Rue Dronot, Paris, Bleaching Engineer.
- Dewar, Prof. J., F.R.S., Royal Institution, Albemarle Street, W. (for Journals); and 1, Scepote Terrace, Cambridge, Professor of Chemistry and Physics.
- Dewar, Jno. A., Melrose House, Perth, N.B., Distiller.
- Dewey, Fred. P., 702, 9th Street Northwest, Washington, D.C., U.S.A., Metallurgist.
- De Wilde, Prof. P., 339, Avenue Louise, Brussels, Belgium, Professor of Chemistry.
- Dey, Prem Lal, 4, Beadon Street, Calcutta, Manufacturing Chemist.
- Dibdin, W. J., London County Council, 40, Craven Street, London, S.W.; and (Journals) Mayfield Grauge Road, Sutton, Surrey, Analytical Chemist.
- Dick, A., 110, Cannon Street, London, E.C., Chemical Engineer.
- Dickerson, E. N., 15, Wall Street, New York, U.S.A., Lawyer.
- Dickinson, A. J., Neptune Tar and Chemical Works, Deptford, S.E.; and (Journals) 4, Shardeloes Road, New Cross, S.E., Tar Distiller.
- Dickson, Jno., 54, Brown Street, Broomielaw, Glasgow, Oil Merchant.
- Diestel, Wm., 77, William Street, New York, U.S.A., Dyestuff Importer.
- Divers, Dr. E., F.R.S., Rongo, Tokyo, Japan, Professor of Chemistry.
- Dixon, Prof. Harold B., F.R.S., Owens College, Manchester, Professor of Chemistry.
- Dixon, Jos., Spring Grove, near Sheffield, Paper Maker.
- Dixon, M. T., P.O. Box 1816, Johannesburg, S.A.R., Metallurgical Chemist.
- Dixon, Wm., 102, Spring Street, Bury, Lancashire, Science Master.
- Dixon, W. Hepworth, Wingfield, Wainstead, E., Match Works Manager.
- Dobb, Thos., Andrey Cottage, Union Road, Sharrow, Sheffield, Pharmaceutical Chemist.
- Dobbie, Dr. J. J., University College of North Wales, Bangor, Professor of Chemistry.
- Dobbin, Dr. L., Chemical Laboratory, University, Edinburgh, Professor of Chemistry.
- Dodd, A. J., River View, Belvedere, Kent, Oil Refiner.
- Dodd, Archelans, 135, Coleman Street, Whitmorecans, Wolverhampton, Electro-Chemical Foreman.
- Dodd, W. R., Oak Dene, Bush Hill Park, Enfield, N., Chemical Works Manager.
- Doherty, Daniel, Inland Revenue, Hailsham, Sussex, Analytical Chemist.
- Doidge, H., Town Hill, Pietermaritzburg, Natal.
- Domicier, A., 13, St. Mary-at-Hill, London, E.C., Chemical Merchant.
- Donald, George, Arnold Printworks, North Adams, Mass., U.S.A., Printworks Chemist.
- Donald, Jas., 5, Queen's Terrace, Glasgow, Manufacturing Chemist.
- Donald, Samuel, Corporation Gasworks, Dundee, Analytical Chemist.
- Donald, W., Saltecoats, N.B., Analytical Chemist.
- Donald, W. J. A., 40, Lilybank Gardens, Glasgow, Chemical Manufacturer.
- Doolittle, Orrin S., 130, North 5th Street, Reading, Pa., U.S.A., Chemist and General Storekeeper, Philadelphia and Reading Railroad.
- Doran, Robt. E., Chemical Department, Queen's College, Cork, Ireland, Chemical Demonstrator.
- Dore, Jas., Copper Works, High Street, Bromley-by-Bow, E., Distiller's Engineer.
- Dorsey, Grafton D., Atlantic White Lead Works, 135, Marshall Street, Brooklyn, N.Y., U.S.A., Manager.
- Dott, D. B., c/o Duncan, Flockhardt, & Co., 104, South Canongate, Edinburgh, Analytical Chemist.
- Dongall, A., 27, Beverley Road, Hull, Gas Engineer.
- Dougall, Archibald, Gasworks, Kidderminster, Gas Engineer.
- Douglas, London M., 29, Farringdon Road, London, E.C., Chemical Manufacturer.
- Douglas, William, Diamond Plantation, Demerara, British Guiana, Chemical Engineer.
- Doolton, Sir Henry, Lambeth Pottery, London, S.E., Potter.
- Dowling, Edmund, 83, Cable Street, London, E., Oil Merchant.
- Down, T., Tharsis Copper Works, Cardiff, Chemical Manufacturer.
- Dowson, J. Emerson, 3, Great Queen Street, Westminster, S.W., Civil Engineer.
- Drake, Chas. A., Three Mills Distillery, Bromley-by-Bow, E., Brewer.
- Dreaper, W. P., 15, Prince's Road, Great Yarmouth, Technical Chemist.
- Drew, D., Lower House Printworks, near Burnley, Calico Printer.
- Dreyfus, Dr. C., Clayton Aniline Co., Limited, Clayton, Manchester, Dye Manufacturer.
- Dreyfus, S., Clayton Aniline Co., Ltd., Clayton, Manchester, Chemist.
- Driffield, V. C., Appleton, Widnes, Chemical Engineer.
- Drown, Prof. T. M., The Lehigh University, South Bethlehem, Pa., U.S.A., Professor of Analytical Chemistry.
- Drummond, Hon. G. A., Montreal, Canada.
- Dudley, Dr. C. B., 1219, 12th Avenue, Altoona, Pa., U.S.A., Analytical Chemist.
- Dudley, Prof. W. L., Vanderbilt University, Nashville, Tenn., U.S.A., Professor of Chemistry.
- Dufton, Arthur, 81, Watson Road, Broomhill, Sheffield, Teacher of Dyeing.
- Duffield, Dr. S. P., Dearborn, Wayne Co., Mich., U.S.A., Health Officer.
- Duggan, T. R., Sunnybank, Vanbrugh Hill, Blackheath, S.E., Analytical Chemist.
- Dukes, T. William, P.O. Box 210, Johannesburg, S.A.R., Merchant.
- Duncan, Arthur W., 15, Fern Street, Higher Broughton, Manchester, Analytical Chemist.
- Duncan, J., 9, Mining Lane, London, E.C., Sugar Refiner.
- Dunlop, Robt., Stanrigg Oil Works, Airdrie, N.B., Oil Works Manager.
- Dunn, Fred., 306, Flinders Lane, Melbourne, Victoria, Analytical Chemist.
- Dunn, J., 53, Brown Street, Manchester, Chemical Manufacturer.
- Dunn, John, Morgan Academy, Dundee, Science Teacher.
- Dunn, Dr. J. T., Northern Polytechnic, Holloway Road, London, N., Headmaster.
- Dunn, P., 53, Brown Street, Manchester, Chemical Merchant.
- Dunn, W. H., jun., c/o Messrs. Reckitt and Sons, Lim., Hull, Analyst.
- Dupce, H. D., Walpole, Mass., U.S.A., Chemical Agent.
- Dupré, Dr. A., F.R.S., Westminster Hospital Medical School, Caxton Street, London, S.W., Professor of Chemistry.
- Dutton, W. H., 88, Wickham Road, Brockley, S.E., Merchant.
- Duxbury, Thos., 14, Grosvenor Chambers, Deansgate, Manchester, Gas Engineer.
- Dvorkovitch, Dr. P., 6, Willow Bridge Road, Canonbury, N., Technical Chemist.
- Dyer, Dr. B., 17, Great Tower Street, London, E.C., Analytical and Consulting Chemist.
- Dyson, C. E., Flint, North Wales.

Dyson, Dr. G., Temple House, Cheetham Hill, Manchester, Analytical Chemist.
 Dyson, H., West View House, Apperley Bridge, near Leeds, Manufacturing Chemist.
 Dyson, Septimus, West View House, Apperley Bridge, near Leeds, Manufacturing Chemist.

E

Earle, Vava-sour, Porchester Lodge, Streatham Common, S.W., Merchant.
 Earnshaw, Edwin, 24, Mark Lane, London, E.C., Accountant.
 Earp, W. R., Halton Road, Runcorn, Cheshire, Chemical Manufacturer.
 Eastick, C. E., Clyde Wharf Refinery, Victoria Docks, E., Technical Chemist.
 Eastick, J. J., Millaquin Refinery, Bundaberg, Queensland, Sugar Works Manager.
 Eastlake, A. W., 17, Temperley Road, Balham, S.W., Petroleum Works Manager.
 Eastwick, Jos. H., 2202, Venango Street, Philadelphia, Pa., U.S.A., Chemist.
 Eastwood, Chas., Linaere Gas Works, Bootle, near Liverpool, Gas Works Manager.
 Eastwood, Edward, Tunnel Soap Works, Wapping, E., Soap Maker.
 Eddy, Harrison P., Sewage Purification Works, Worcester, Mass., U.S.A., Superintendent.
 Ede, Henry E., (Journals) c/o W. C. Tripler, Coquimbo, Chile; and (subs.) c/o Rev. Moore Ede, The Rectory, Gateshead-on-Tyne, Analytical Chemist.
 Edge, Anthony, Readville, Mass., U.S.A., Chemist.
 Edgell, G. E., 2, Gladstone Terrace West, Gateshead-on-Tyne, Technical Chemist.
 Edmunds, Dr. Lewis H., 1, Garden Court, Temple, E.C., Barrister-at-Law.
 Edwards, Henry W., 514, Utah Avenue, Santa Monica, Cal., U.S.A., Smelting Works Manager.
 Ehrenfeld, Prof. Chas. H., York Collegiate Institute, York, Pa., U.S.A., Professor of Chemistry.
 Ekenberg, Dr. Martin, 3, Agnegatan, Stockholm, Sweden, Technical Chemist.
 Ekman, C. D., Paper Mills, Northfleet, Kent, Technical Chemist.
 Elborough, T., 59, Mark Lane, London, E.C., Manure Manufacturer.
 Elliot, John, Free Library, Wolverhampton, Librarian.
 Elliott, Dr. A. H., Consolidated Gas Co., 4, Irving Place, New York, U.S.A., Analytical Chemist.
 Elliott, Dr. J. F., c/o Grimwade and Co., 82, Bishopsgate Street, London, E.C., Manufacturing Chemist (Sydney, N.S.W.).
 Ellis, Alex., Victoria Terrace, South Shields, Pharmaceutical Chemist.
 Ellis, C. J., 13, West Scotland Street, Kinning Park, Glasgow, Technical Chemist.
 Ellis, E. Victor, 21, Castle Street, Edinburgh, Analytical Chemist.
 Ellis, G. Beloe, 6, Westbourne Terrace, Hyde Park, W., Patent Agent.
 Ellis, H., 112, Regent Street, Leicester, Chemical Merchant.
 Ellis, Prof. W. Hodgson, School of Practical Science, Toronto, Canada, Professor of Applied Chemistry.
 Ellison, Henry, Flatt Lane, Cleckheaton, Yorks, Manufacturing Chemist.
 Elmore, A. S., Knostrop Old Hall, Leeds, Electro-Metallurgist.
 Elworthy, H. S., 19, Hill Road, Bandra, Bombay, India, Sugar Works Chemist.
 Emanuel, J. F., 178, North 11th Street, Brooklyn, N.Y., U.S.A., Varnish Manufacturer.
 Emmens, S. H., Amador City, Cal., U.S.A., Chemical Engineer.
 Endemann, Dr. H., 23, William Street, New York City, U.S.A., Analytical Chemist.
 Enequist, John, 502, Clinton Avenue, Brooklyn, N.Y., U.S.A., Consulting Chemist and Chemical Engineer.
 England, R. J., Broomhill Lodge, Woodford Green, E., Chemical Manufacturer.
 English, Frank H., 16, Green Terrace, Padiham, Lancashire, Analytical Chemist.
 Entwisle, Edw., Woodlands, Ashton-upon-Mersey, Cheshire, Cotton Manufacturers.
 Ermen, F., jun., Nassau Mills, Patricroft, Manchester, Dyer and Bleacher.
 Erns, Adolf, Oberlangenbielau, Schlesien, Germany, Chemist.
 Erskine, J. K. (Subscriptions), 6, Lascotts Road, Wood Green, N.4 and (Journals), Geo. Goeh G. M. Co., Box 540, Johannesburg, S.A.R., Analytical Chemist.
 Esiltman, A., 25, Roe Lane, Southport, Lancashire, Analytical Chemist.
 Estcourt, C., 20, Albert Square, Manchester, Consulting Chemist.
 Evans, Enoch, 181, Herbert Road, Small Heath, Birmingham, Accountant.
 Evans, Sir John, K.C.B., F.R.S., Nash Mills, Hemel Hempstead, Herts, Paper Maker.
 Evans, Jno., H., 71, Lambton Road, Cottenham Park, Wimbledon, Analytical Chemist.
 Evans, R. E., 3, Glencoe, Stratford-on-Avon, Brewing Chemist.
 Evershed, F., Atlas Works, Hackney Wick, London, E., Colour Chemist.
 Evershed, Henry G., Soap Works, Foundry Street, Brighton, Soap Maker.
 Evershed, Wallis, c/o Whitwell & Co., Ltd., Kendal, Westmoreland, Brewer's Chemist.
 Ewan, Dr. Thos., The Yorkshire College, Leeds, Teacher of Chemistry.
 Exley, Arthur, Meanwood Grove, Meanwood, near Leeds, Tanner.
 Eyckens, Osear, 14, Rue Bleue, Paris, France, Chemical Manure Manufacturer.

F

Fahlberg, Dr. C., Saccharin fabrik, Salbke-Westerhusen a Elbe, Germany, Manufacturing Chemist.
 Fairchild, Sam W., King's Bridge, N.Y., U.S.A., Manufacturing Chemist.
 Fairley, T., 17, East Parade, Leeds, Analytical Chemist.
 Fairlie, H. C., 2, University Gardens, Glasgow, Chemical Manufacturer.
 Fairweather, Wallace, 62, St. Vincent Street, Glasgow, Patent Agent.
 Fallon, J. H. M., c/o Peruvian Corporation, Ltd., Lima, Peru, Analytical Chemist.
 Fallowfield, T., Calico Printer.
 Fanta, F., Effingham House, Arundel Street, Strand, W.C., Engineer.
 Farrant, N., c/o J. Nicholson and Sons, Chemical Works, Hunslet, Leeds, Analytical and Metallurgical Chemist.
 Farries, T., 16, Coleman Street, London, E.C., Manufacturing Chemist.
 Farrington, T., 4, Waterloo Place, Cork, Ireland, Chemical Engineer.
 Fasnacht, A. E., 296, Ashton New Road, Clayton, Manchester, Chemist.
 Faulkner, F., The Laboratory, Bath Row, Birmingham, Consulting Brewer's Chemist.
 Fawcett, Jas. H., c/o Bank of Australasia, Perth, West Australia, Metallurgist.
 Fawsitt, C. A., Atlas Chemical Works, East Nelson Street, Glasgow, Chemical Manufacturer.
 Feld, Walther, Chemische Fabrik, Hönningen a/Rhein, Germany, Chemical Works Director.
 Fellowes, F. W., 61-62, Chancery Lane, London, W.C., Consulting Brewer's Chemist.
 Ferguson, J. Hart, Loch Katrine Distillery, Camlachie, Glasgow, Distillery Manager.
 Ferguson, Prof. J., The University, Glasgow, Professor of Chemistry.

- Fergusson, H., Prince Regent's Wharf, Victoria Docks, E., Technical Chemist.
- Ferguson, Wm. B., 3, Plowden Buildings, Temple, E.C., Barrister-at-Law.
- Ferrie, And., Roslin House, Ellesmere Park, Eccles, Manchester, Chemical Merchant.
- Fiebing, John H., 644, 28th Street, Milwaukee, Wis., U.S.A., Leather Trade Chemist.

- Freestone, J. W., 9, Clark's Terrace, New Ferry, Cheshire, Manufacturing Chemist.
- Frew, Dr. Wm., Laboratory, Well Park Brewery, Glasgow, Brewing Chemist.
- Fries, Dr. Harold H., 92, Reade Street, New York, U.S.A., Chemical Manufacturer.
- Friswell, R. J., 115, Darenth Road, Stamford Hill, London, N., Colour Manufacturer.
- Frost, Dr. Howard V., Arlington, Mass., U.S.A., Professor of Chemistry.
- Frost, Joe, Mold Green, Huddersfield, Manufacturing Chemist.
- Fryer, Dr. A. C., 13, Eaton Crescent, Clifton, Bristol, Alkali Works Inspector.
- Fuerst, Dr. Alex. F., c/o Wood Street Smelting Works, 30, Wood Street, London, E.C., Chemist.
- Fuerst, Jos. F., 17, Philpot Lane, London, E.C., Chemical and Oil Merchant.
- Fuerst, W. F., 2, Stone Street, New York, U.S.A., Chemical Merchant.
- Fuller, Chas. J. P., L. and V. Railway Works, Horwich, near Bolton, Analytical Chemist.

Fuller, W. M. (Journals), Lawn Side, Stow Park Circus, Newport, Mon.; and (subscription) c/o Morris & Griffin, Lim., Maindee, Newport, Mon., Chemical Manufacturer.
 Fulton, H. B., 33, St. Dunstan's Road, West Kensington, S.W., Metallurgist.
 Fulton, Robt., jun., Ardeer Factory, Stevenston, Ayrshire, N.B., Explosives Chemist.
 Furness, H. B., Smith and Augusta Streets, Cincinnati, Ohio, U.S.A., Chemist.
 Fyfe, Jno., 7, West George Street, Glasgow, Oil Works Director.

G

Gabbett, E. R., Prince Regent's Wharf, Victoria Docks, London, E., Chemical Engineer.
 Gadsden, Capt. H. A., Chemical Merchant.
 Gair, Wm., 125, Frederick Road, Aston, Birmingham, Analytical Chemist.
 Gajjar, Professor T. K., Temple of Art, Baroda, India, Professor of Chemistry.
 Galbraith, Wm., West Park, Saltergate, Chesterfield, Technical Chemist.
 Gall, Henry, L'Usine de Produits Chimiques de Villers par Hermes, Oise, France, Technical Chemist.
 Galt, Hugh Allen, c/o Michigan Alkali Co., Wyandotte, Mich., U.S.A., Works Manager.
 Gamble, Col. D., Windlehurst, St. Helens, Chemical Manufacturer.
 Gamble, D., jun., Ratonagb, Colwyn Bay, North Wales, Chemical Manufacturer.
 Gamble, J. C., Cowley Hill, St. Helens, Chemical Manufacturer.
 Gamble, Jas. N., The Laboratory, Procter and Gamble Co., Ivorydale, Ohio, U.S.A., Soap Manufacturer and Oil Refiner.
 Gamble, W., Briars Hey, Rainhill, near Liverpool, Chemical Manufacturer.
 Gane, Eustace H., 79, Ann Street, New York, U.S.A., Pharmaceutical Chemist.
 Gans, Adolf, Farbenfabrik von L. Cassella & Co., Frankfurt o/Main, Germany, Dye Works Manager.
 Gardiner, H. J., 48, Clovelly Mansions, Gray's Inn Road, W.C., Traveller.
 Gardner, Walter M., Technical College, Bradford, Yorks., Assistant Lecturer on Dyeing.
 Garibaldi, Joachim A., 21, Church Place, Gibraltar, Analytical Chemist.
 Garner, D. C., Syston, Leicester, Manufacturing Chemist.
 Garrett, F. C., Durham College of Science, Newcastle-on-Tyne, Teacher of Science.
 Garrick, Dr. A. R., Huyton, near Liverpool, Manufacturing Chemist.
 Garton, R. (Hill, Garton & Co.), Southampton Wharf, Battersea, S.W., Glucose Manufacturer.
 Garton, Rd. S., 7, Cavendish Road, Birmingham, Chemist.
 Gascoyne, Dr. W. J., 36, South Holliday Street, Baltimore, Md., U.S.A., Analytical Chemist.
 Gaskell, H., jun., Clayton Lodge, Aigburth, near Liverpool, Alkali Manufacturer.
 Gaskell, Holbrook, Woolton Wood, Liverpool, Alkali Manufacturer.
 Gaskell, J., 1, Woodlands Road, Cheetham Hill, Manchester, Analytical Chemist.
 Gate, Tom Erskine, Messrs. Howroyd and Oldroyd, Dewsbury, Yorks., Manufacturing Chemist.
 Gathral, G., 174, Soho Hill, Handsworth, Birmingham.
 Geisler, Dr. Jos. F., New York Mercantile Exchange Building, 6, Harrison Street, New York, U.S.A., Consulting Chemist.
 Gemmell, G. H., 4, Lindsay Place, George IV. Bridge, Edinburgh, Analytical Chemist.
 Gendall, W. H. S., Gas Works, Elton, Bury, Gas Engineer.
 Georgi, Carl, 77, John Street, New York, U.S.A., Aniline Colour Importer.
 Gerland, Dr. B. W., 4, Denmark Place, Acerington, Consulting Chemist.
 Gibb, Thos., Hunt's Cross, Liverpool, Metallurgist.

Gibbins, H. B., 177, Redland Road, Bristol.
 Gibbs, D. Cecil, 16, Finsbury Circus, London, E.C., Soap Manufacturer.
 Gibbs, R. D., 320, Clapham Road, London, S.W., Works Manager.
 Gibbs, W. P., 7, Kingsland Road, Canton, Cardiff, Analytical Chemist.
 Gibson, Dr. J., 20, George Square, Edinburgh, Chemical Lecturer.
 Gibson, J. M., c/o Buckley Brick and Tile Co., Buckley, via Chester, Brick and Tile Manufacturer.
 Gilbert, Francis, The Laboratory, 17, Great Tower Street, E.C., Analytical Chemist.
 Gilbert, Sir Jos. H., F.R.S., Harpenden, near St. Albans, Agricultural Chemist.
 Gilchrist, P. C., F.R.S., Frogual Bank, Finchley New Road, Hampstead, N.W., Metallurgist.
 Gilchrist, Peter S., Blacksburg, S.C., U.S.A., Chemical Engineer.
 Giles, W. B., 1, The Avenue, Church Road, Leyton, E., Chemical Works Manager.
 Gill, Dr. Aug. H., Massachusetts Institute of Technology, Boston, Mass., U.S.A., Assistant Professor of Gas Analysis.
 Gillman, Gustave, A.M.I.C.E., Ferro-carriil de Mureia á Granada, Aguilas, Prov. de Mureia, Spain, Civil Engineer.
 Gilmonr, J. D., 142, Aitkenhead Road, South Side, Glasgow, Chemist.
 Gimingham, Edw. A., Stamford House, Northumberland Park, Tottenham, N. (Edison Swan United Electric Light Co., Lim.), Technical Adviser.
 Girdwood, Dr. G. P., 82, University Street, Montreal, Canada, Professor of Chemistry.
 Gladstone, Dr. J. H., F.R.S., 17, Pembroke Square, London, W., Professor of Chemistry.
 Glaeser, F. A., Carpenter's Road, Stratford, E., Varnish Manufacturer.
 Glaser, Chas., 412, East Lombard Street, Baltimore, Md., U.S.A., Manufacturing Chemist.
 Glatz, Jos., Riverside Chemical Works, 485—493, Kent Avenue, Brooklyn, N.Y., U.S.A., Chemical Manufacturer.
 Glen, Chas., Glengowan Printworks, Calderernix, N.B., Calico Printer.
 Glen, J., jun., Glengowan Printworks, Calderernix, N.B., Calico Printer.
 Glendinning, H., Mount House, The Hill, Sandbach, Cheshire, Technical Chemist.
 Glendinning, Tom A., The Brewery, Leeds, Brewing Chemist.
 Glenn, Wm., Baltimore Chrome Works, 1348, Bloek Street, Baltimore, Md., U.S.A., Chrome Manufacturer.
 Glog, Robt. F., Grove Hill, Middlesbrough, Secretary.
 Glover, G. T., The Phospho Guano Co., Limited, Seacombe, Cheshire, Chemical Works Manager.
 Glover, John, 20, Holly Avenue, Newcastle-on-Tyne, Chemical Engineer.
 Glover, T., Messrs. Mort, Liddell & Co., Widnes, Technical Chemist.
 Glover, W., 20, Holly Avenue, Newcastle-on-Tyne, Technical Chemist.
 Goldschmidt, Dr. S. A., 43—51, Sedgwick Street, Brooklyn, N.Y., U.S.A., Chemical Manufacturer.
 Goodall, Reginald, Camden Works, Camden Town, N.W., and (Journals) The Grove, Pinner, Manufacturing Stationer.
 Goodall, Thos., Hendon Grange, Sunderland, Paper Manufacturer.
 Goodall, Walter, Alma House, Pudsey, near Leeds, Analytical Chemist.
 Goodwin, C. C., The White House, St. John's Road, Bowdon, Cheshire, Soapmaker.
 Goodwin, Dr. W. L., The School of Mining, Kingston, Canada, Professor of Chemistry.
 Goppelsroeder, Dr. F., Mulhausen, Elsass, Germany, Colour Chemist.
 Gordon, J. G., The Mannesmann Tube Co., Ltd., 110, Cannon Street, London, E.C., Steel Manufacturer.

- Gore, Dr. G., F.R.S., 67, Broad Street, Birmingham, Metallurgist.
- Gorvin, Jno. C., English Crown Spelter Works, Port Tennant, Swansea, Assayer.
- Goskirk, Alex., 28, Hillside Street, Edinburgh, Electro-metallurgist.
- Gossage, F. H., Widnes, Alkali Manufacturer.
- Goulding, Wm. Joshua, 25, Eden Quay, Dublin, Manure Manufacturer.
- Gow, R. J., The Cedars, Hough Green, near Widnes, Metallurgical Chemist.
- Gowland, W., 13, Russell Road, Kensington, W., Assayer and Metallurgist.
- Goyder, G. A., Ootalinka, Hawker's Road, Medindie, near Adelaide, South Australia, Chemist (Adelaide School of Mines).
- Grahfield, Dr. J. P., 1915, Indiana Avenue, Chicago, Ill., U.S.A., Chemist.
- Gracey, R., Faircombe, The Barnfield, Exeter, Tobacco Manufacturer.
- Graesser, R., Cefn, near Ruabon, North Wales; and Argoed Hall, Llangollen, North Wales, Manufacturing Chemist.
- Graham, Dr. C., 23, Easton Buildings, Gower Street Station, London, N.W., Consulting Chemist.
- Graham, C. C., c/o Blundell, Spence & Co., Beverley Road, Hull, Technical Chemist.
- Grandage, H., Calder Dye Works, Brighonse, near Leeds, Dyer.
- Gratama, Dr. W. D., Huize Kraayenburg, Ryswyk, Z.H., Holland, Professor of Chemical Technology.
- Graves, Geo. H., Fairfield Chemical Works, Bridgeport, Conn., U.S.A., Manufacturing Chemist.
- Gray, Elisha B., New Brighton, Richmond Co., N.Y., U.S.A., Oil Inspector and Chemist.
- Gray, G. Watson, Chemical Laboratory, 13, North John Street, Liverpool, Consulting Chemist and Assayer.
- Gray, Jno., Pentland Oil Works, Loanhead, N.B., Oil Works Chemist.
- Gray, Parker, Towerfield, Clarendon Road, Watford, Herts., Oil and Tallow Merchant.
- Gray, W., Cliff House, Barton-on-Humber, Oil Refiner.
- Greaves, I. A. R., The Old Rectory, Grappenhall, Cheshire, Brewer.
- Greaves, Wm., Powell Duffryn Steam Coal Co., Aberaman, Aberdare, South Wales, Chemical Engineer and Chemist.
- Greeff, Robt. W., 3, Eastcheap, London, E.C., Chemical Agent.
- Green, Alfred H., Oaklands, Lowton, Newton-le-Willows, Lancashire, Manufacturing Chemist.
- Green, A. G., 13, King's Drive, Heaton Moor, near Stockport, Colour Chemist.
- Green, H., Hayle Mill, Maidstone, Paper Manufacturer.
- Green, Joo. Edw., 1, Queen's Road, Urmston, near Manchester, Soap Works Manager.
- Green, L., Lower Tovil, Maidstone, Paper Manufacturer.
- Green, Samuel, 28 and 29, St. Swithin's Lane, London, E.C., Chemical Auctioneer.
- Greenaway, A. J., Fregnal, Hampstead, N.W., Sub-Editor of Chemical Society's Journal.
- Greenhalgh, J. Herbert, Shepherd's, Tottington Mill, near Bury, Assistant Manager of Printworks.
- Greenhough, D. W., 5, Rood Lane, London, E.C., Chemical Broker.
- Greenway, T. J., Harrow Road, East Adelaide, South Australia, Metallurgist.
- Greenwood, H., 411, Blackburn Road, Acerrington, Technical Chemist.
- Gregory, Wm. J., 1, St. John's Terrace, Weymouth, Dorset, Chemist.
- Greville, H. L., Diersheim, Churchfields, Woodford, Essex, Gas Examiner.
- Griffin, John R., 22, Garrick Street, Covent Garden, W.C., Chemical Apparatus Maker.
- Griffin, Martin L., Mechanicville, Saratoga Co., N.Y., U.S.A., Analytical Chemist (and Consulting) (Fibre, Paper, Clays).
- Griffith, D. Agnew, c/o The Bonnington Sugar Co., Ltd., Leith, N.B., Technical Chemist.
- Griffith, R. W. S., Eyeworth Lodge, Lyndhurst, Hants, Gunpowder Manufacturer.
- Griffiths, Thos., The Cedars, Clapham Common, S.W., Manufacturing Chemist.
- Grime, J., Rosebank Cottage, Busby, near Glasgow, Calico Printer.
- Grimshaw, H., Thornton View, Clayton, Manchester, Chemical Manufacturer.
- Grimwood, R., 41, Lady Margaret Road, London, N.W., Analytical Chemist.
- Grindley, J., Upper North Street, Poplar, London, E., Tar Distiller.
- Gripper, Harold, Stores Department, M. S. and L. Railway, Gorton, Manchester, Analytical Chemist.
- Gronow, W. T., Port Pirie Smelting Works, Port Pirie, South Australia, Metallurgist.
- Grossmann, Dr. J., Harpurhey Chemical Works, Manchester, Chemical Manufacturer.
- Groves, C. E., F.R.S., 352, Kennington Road, London, S.E., Editor of Chemical Society's Journal.
- Gulliver, Geo. W., Prince Regent's Wharf, Silvertown, E., Chemist.
- Gunn, W. L., Broad Plain Soap Works, Bristol, Analytical Chemist.
- Gurney, J. Clare, Fabrice Roma, La Union, Prov. de Murcia, Spain, Analytical Chemist.
- Guthrie, John A., 34, Lancaster Park, Richmond, Surrey, Chemical Merchant.
- Guthrie, John, 50, Prospect Terrace, Hunslet Moor, Leeds, Chemical Works Manager.
- Guttmann, Oscar, 110, Adelaide Road, N.W., Explosives Engineer.
- Gayatt, T., Ceara Gas Co., Limited, 9, Queen Street Place, Cannon Street, London, E.C., Secretary.

H

- Habirshaw, W. M., 315, Madison Avenue, New York City, U.S.A., Chemical Engineer.
- Hacking, W. H., The Grange, Clayton-le-Moors, near Acerrington.
- Haddow, A., 1, Easter Road, Edinburgh, Mechanical Engineer.
- Hadfield, R. A., Newhall Road, Attercliffe, Sheffield, Steel Founder.
- Hadkinson, E., Pamphila Oil and Soap Works, Mitylene, Mediterranean, Oil Refiner and Soap Manufacturer.
- Hadkinson, R., Smyrna, Asia Minor, Oil Refiner.
- Hadley, Walter S., Millersdale, Sutton, St. Helens, Lancashire, Plate Glass Maker.
- Haga, Tanemasa, Chemical Department, Science College, Imperial University, Tokyo, Japan, Chemical Demonstrator.
- Haig, Robert, Mechanical Retorts Co., Limited, Murray Street, Paisley, N.B., Chemical Engineer.
- Haigh, Ben, 21, Cavendish Road, Leeds, Dyer and Dyewood Extract Maker.
- Hailes, A. J., de 15, Red Lion Square, W.C., Analytical Chemist.
- Haines, Reuben, 201, South 5th Street, Philadelphia, Pa., U.S.A.; and (Journals) Haines Street, near Chew Street, Germantown, Philadelphia, Pa., U.S.A., Analytical Chemist.
- Hake, C. N., Department of Trade and Customs, Melbourne, Victoria, Inspector of Explosives.
- Hale, Edw. P., c/o Wakefield & Co., Gatebeck, Kendal, Analytical Chemist.
- Hall, Allan T., c/o Sissons Bros. & Co., Ltd., Hull, Oil Refiner and Varnish Manufacturer.
- Hall, Archibald D., 31, Bishop-gate Street, London, E.C., Analytical Chemist.
- Hall, Edgar, Rivertree, via Stanthorpe, Queensland, Technical Chemist.

- Hall, Jno. A., Victoria Chemical Works, Victoria, British Columbia, Analytical Chemist.
- Hall, Jas. W., Bombay, Baroda, and Central India Railway, Parell, Bombay, India, Linseed Oil Mills Manager.
- Hall, R. E., Box 12, Johannesburg, South African Republic, Assayer.
- Hall, S., East London Soap Works, Bow, London, E., Soap Manufacturer.
- Haller, Geo., Sussex House, 52, Leadenhall Street, London, E.C., Chemical Merchant.
- Haller, H. Loft, 27, Hilda Street, Beverley Road, Hull, Analytical Chemist.
- Halliwell, Edw., Alexandra Crescent, Dewsbury, Yorks., Analyst.
- Hamaguchi, K., Hiro Mura, Arito Gori, Wakayama Ken, Japan, Soy Manufacturer.
- Hamburger, Aron, North Wales, Pa., U.S.A., Technical Chemist.
- Hamilton, Dr. Claude C., 913, East Tenth Street, Kansas City, Mo., U.S.A., Chemist and Assayer.
- Hamilton, David R., 19, Graham Street, Bridgeton, Glasgow, Dyer.
- Hamilton, Jas. C., Arncliffe, Arnside, via Carnforth, Chemical Works Manager.
- Hamilton, Oswald, c/o The British White Lead Co., Northfleet, Kent, Chemical Engineer.
- Hamilton, Robert, c/o Furnace Gases Co., Ltd., Shotts, N.B., Works Manager.
- Hamilton, Robt., Leeds Steelworks, Ltd., Leeds, Analytical Chemist.
- Hamlen, G. J., c/o Hercules Powder Co., Ashburn, Mo., U.S.A., Analytical Chemist.
- Hammerley, W. A. L., Bridge House, Leek, Staffordshire, Dyer.
- Hammill, M. J., 9, Windle Street, St. Helens, Alkali Manufacturer.
- Hammond, Geo. W., Yarmouthville, Maine, U.S.A., Paper Co.'s Agent.
- Hammond, J., Gas Works, Eastbourne, Sussex, Gas Manager.
- Hampson, Benj. A., Lonsdale House, 9, College Road, Brighton, Chemist and Assayer.
- Hand, T. W., Public Library, Oldham, Librarian.
- Handy, Jas. O., c/o Hunt and Clapp, Pittsburg, Pa., U.S.A., Chemist.
- Hanks, Abbot A., 718, Montgomery Street, San Francisco, Cal., U.S., Assayer.
- Hanson, A. M., Abbey Printworks, Whalley, Blackburn, Print Works Chemist.
- Hanson, John, Highfield Villa, Belle Vue, Wakefield, Manufacturing Chemist.
- Harden, Arthur, Ashville, Upper Chorlton Road, Manchester, Lecturer in Chemistry.
- Hardie, William, The Gas Offices, Newcastle-on-Tyne, Gas Engineer.
- Hardman, Josiah, Milton Chemical Works, Stoke-on-Trent, Chemical Manufacturer.
- Hardman, Richard B., Fernhill Mills, Bury, Lancashire, Woollen Manufacturer.
- Hargreaves, Jas., Farnworth, Widnes, Lancashire, Chemical Engineer.
- Hargreaves, Jno., Widnes, Alkali Manufacturer.
- Hargreaves, Mark, 108, Fylde Road, Preston, Manufacturing Chemist.
- Harkness, W., The Laboratory, Somerset House, London, W.C., Analytical Chemist.
- Harland, R. H., Plough Court, 37, Lombard Street, London, E.C., Consulting Chemist.
- Harlock, E. B., Newton Farm, Middlewich, Chemical Manufacturer.
- Harmon, L. E., 46-54, Fulton Street, Buffalo, N.Y., U.S.A., Analytical Chemist.
- Harned, Frank P., 1332, Washington Avenue, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
- Harrington, W. B., Ardsullagh, Old Blackrock Road, Cork, Chemical Manufacturer.
- Harris, Arthur, Marsh Gate Works, Stratford, E., Soap Maker.
- Harris, Booth, jun., Hillside, Loughton, Essex, Soap Maker.
- Harris, D., Caroline Park, Edinburgh, Chemical Manufacturer.
- Harris, Sydney J., School of Science, Rossington Street, Leeds, Science Teacher.
- Harris, Sydney W., 15, Lansdowne Terrace, Walters Road, Swansea, Assayer.
- Harrison, A., Thames Sugar Refinery, Silvertown, London, E., Sugar Works Chemist.
- Harrison, C., Hayle, Cornwall, Technical Chemist.
- Harrison, Dr. Franklin T., London, Ontario, Canada, Public Analyst.
- Harrison, G. D., Netham Chemical Works, Bristol, Chemical Manufacturer.
- Harrison, G. H., Hagley, near Stourbridge, Firebrick Maker.
- Harrison, G. King, Hagley, near Stourbridge, Fireclay Mine Owner.
- Harrison, J., Madore, Ballintemple, Cork, Chemical Engineer.
- Harrison, J. Arnold, 4, Kyverdale Road, Stoke Newington, N., Chemical Manufacturer.
- Harrison, Jno., 35th and Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemical Manufacturer.
- Harrison, Prof. John B., Government Laboratory, Georgetown, British Guiana, Government Analyst.
- Harrison, M. C. C., Haverbrack, Bishop's Stortford, Herts.
- Hart, Bertram H., The Elms, Old Charlton, S.E., Analytical Chemist.
- Hart, Dr. E., Lafayette College, Easton, Pa., U.S.A., Professor of Chemistry.
- Hart, H. W., c/o J. G. and G. Potter and Co., Darwen, Lancashire, Analytical Chemist.
- Hart, P., c/o Tennants & Co., Clayton, Manchester, Technical Chemist.
- Hartford, Jas., 3, Cedar Street, New York, U.S.A., Aniline Merchant.
- Hartley, Arthur, Cannon Brewery, Brighton, Brewer.
- Hartley, Joseph, Ballavartyn, Santon, near Douglas, Isle of Man, Technical Chemist.
- Hartley, R. Kent, Springwood House, Chadderton, near Oldham, Chemical Works Manager.
- Hartley, Prof. W. N., F.R.S., Royal College of Science, Dublin, Professor of Chemistry.
- Hartog, Philip J., Owens College, Manchester, Analytical Chemist.
- Hartridge, Jas. Hills, Holnwood, Hendon Manufacturing Chemist.
- Harvey, E. Feild, Omrae, St. John's, Newfoundland, Chemist.
- Harvey, Ernest W., 39, Alderbrook Road, Balham, S.W., A.R.S.M. Engineer.
- Harvey, H. C., Raglan House, Brooklands, near Manchester, Chemist.
- Harvey, Sidney, South-Eastern Laboratory, Canterbury, Analytical Chemist.
- Harvey, T. H., Cattedown, Plymouth, Chemical Manufacturer.
- Harzer, C. A., Billiter Buildings, Billiter Street, London, E.C., Merchant.
- Hasenclever, R., Chemische Fabrik-Rhenania, Aachen, Prussia, Chemical Manufacturer.
- Hastings, Hugh, 55, Comberton Road, Kidderminster, Analytical Chemist.
- Hatfield, Jno. A., 89, Bridge Street, Wednesbury, Staffordshire, Analytical Chemist.
- Hathaway, Nath., New Bedford, Mass., U.S.A., Analytical Chemist.
- Hatschek, M., 51, Fulham Park Gardens, Fulham, S.W., Chemical Engineer.
- Hatton, Wm. P., c/o W. R. Hatton & Sons, Wormwood Scrubs, W., Starch Works Manager.
- Hauff, Julius, Lrhanstrasse 56, Stuttgart, Germany, Chemical Manufacturer.
- Hawker, E. W., Adelaide Club, Adelaide, South Australia, Metallurgist.
- Hawkins, H., Eyeworth Lodge, Lyndhurst, Hants, Chemical Works Manager.
- Hawkins, J. Dawson, The El Paso Reduction Company, Gillett, Col., U.S.A., Smelting Works Manager.
- Hawliczek, Josef, 34, Linnet Lane, Sefton Park, Liverpool, Technical Chemist.

- Hay, Alex. B., Kelvindock Chemical Works, Maryhill, Glasgow, Manufacturing Chemist.
- Haynes, David O., 106, Fulton Street (P.O. Box 1483), New York, U.S.A., Proprietor of "Pharmaceutical Era."
- Hays, Jos. A., c/o Chas. Roome Parmele Company, 98, William Street, New York, U.S.A., Chemist.
- Heal, Carlton, Hertford Lodge, Church End, Finchley, N., Chemical Student.
- Healy, A. Augustus, 90, Gold Street, New York, U.S.A., Tanner.
- Heap, Chas., Caldershaw, near Rochdale, Dyer.
- Heap, Isaac H., Fern Bank, Aynsley Road, Stoke-on-Trent, Pharmaceutical Chemist.
- Heap, L., Stacksteads, near Manchester, Manufacturing Chemist.
- Heape, Chas., 19, George Street, Manchester, Calico Printer.
- Heath, R. C., Myton Grange, near Warwick, Chemical Manufacturer.
- Hebden, Jno. C., P.O. Box 824, Providence, R.I., U.S.A., Works Manager and Chemist.
- Hecht, Jos., 2667, Commercial Street, Ravenswood, Ill., U.S.A., Analytical Chemist.
- Hecker, Paul, 102, Fenchurch Street, London, E.C., Chemical Merchant.
- Heckmann, C., 9, Görlitzerufer, Berlin, S.O., Germany, Chemical Apparatus Maker.
- Hedley, Armorer, Mayfield, Gosforth, Newcastle-on-Tyne, Soap Manufacturer.
- Hedley, Geo. H., 2, Croxeth Road, Prince's Park, Liverpool, Chemical Manufacturer.
- Hedley, John, jun., Brabant House, Philpot Lane, E.C.; and (Journals) 21, Russell Chambers, Bloomsbury, W.C., Chemical Merchant.
- Heerlein, Robert, Pennsylvania Salt Manufacturing Co., Natrona, Pa., U.S.A., Salt Works Chemist.
- Hefford, Geo., King Alfred's Grammar School, Wantage, Berks, Chemical Instructor.
- Hehner, O., 11, Billiter Square, London, E.C., Analytical and Consulting Chemist.
- Heisch, Godfrey P., 325, Clapham Road, London, S.W., Gas Engineer.
- Hellier, E. A., 111, Westbourne Avenue, Hull, Varnish Manufacturer.
- Hellon, Dr. R., 47, New Lowther Street, Whitehaven, Analytical and Consulting Chemist.
- Helm, H. J., Simonstone, Hammelton Road, Bromley, Kent, Superintending Analyst (Somerset House).
- Hemingway, H., 60, Mark Lane, London, E.C., Chemical Manufacturer.
- Hempleman, F. S., Wennington House, Wennington, Romford, Essex, Manure Manufacturer.
- Henderson, Jos., 13, Denmark Street, Darlington, Analyst.
- Henderson, Norman M., Broxburn Lodge, Broxburn, N.B., Oil Works Manager.
- Henderson, Prof. G. G., The Technical College, George Street, Glasgow, Professor of Chemistry.
- Henderson, W. F., Moorfield, Claremont Gardens, Newcastle-on-Tyne.
- Hendriebs, Frank H., Imperial Wharf, 46, Bankside, London, S.E., Chemical Merchant.
- Hendrick, Jas., Agricultural Department, 60, John Street, Glasgow, Lecturer on Agricultural Chemistry.
- Hennin, Alphonse, Monongahela Furnaces, McKeesport, Pa., U.S.A., Metallurgical Chemist.
- Henshaw, Jno., Green Lane, Brook Street, Manchester, Soap Manufacturer.
- Henshaw, Sam., Staffordshire Chemical Company, Limited, Tunstall, Stoke-on-Trent, Chemical Works Manager.
- Hepburn, J. G., Priory Works, Dartford, Kent, Leather Manufacturer.
- Herf, O., Herf & Frerichs Chemical Co., St. Louis, Mo., U.S.A., Chemical Manufacturer.
- Heriot, James, 18, Dumbiedykes Road, Edinburgh, Mineral Water Manufacturer.
- Herman, W. D., Eccleston Park, Prescott, Lancashire, Glass Works Chemist.
- Heron, J., 110, Fenchurch Street, London, E.C., Glucose Chemist.
- Herriot, Wm. Scott, 187, Osmaston Road, Derby, Sugar Works Engineer.
- Herrmann, R. W. (Herrmann, Keller & Co.), 102, Fenchurch Street, London, E.C., Chemical Merchant.
- Hersam, Ernest A., State University, College of Mines, Berkeley, Cal., U.S.A., Assistant in Sanitary Chemistry.
- Herschel, Prof. A. S., F.R.S., Observatory House, Slough, Bucks, Hon. Professor of Experimental Physics.
- Herzmann, Dr. M., c/o Kris, III. Hetzgasse 10, Vienna, Austria, Technical Chemist.
- Hesketh, Everard, Dartford Ironworks, Dartford, Kent, Civil Engineer.
- Heslop, Oliver, Allhusen's Works, Gateshead-on-Tyne, Analytical Chemist.
- Hess, Dr. Adolph, Oil Works, Leeds, Chemical Manufacturer.
- Hetherington, Dr. Albert E., Ammonia Soda Works, Fleetwood, Lancashire, Analytical Chemist.
- Hewitt, A. H., The Green Island Cement Co., Lim., Hong Kong, China, Engineer.
- Hewitt, Dr. D. B., Oakleigh, Northwich, Cheshire, Alkali Manufacturer.
- Hewlett, John C., 40-42, Charlotte Street, Great Eastern Street, London, E.C., Manufacturing Chemist.
- Hey, Harry, Queen's Mills, Savile Town, Dewsbury, Dyer.
- Heyden, Dr. F. von, Chemische Fabrik, Radebeul, bei Dresden, Germany, Salicylic Acid Manufacturer.
- Heyl, J. Edw., 38, Bury New Road, Higher Broughton, Manchester, Chemical and Electrical Engineer.
- Heys, W. E., 70, Market Street, Manchester, Engineer and Patent Agent.
- Heys, Z. J., Stonehouse, Barrhead, N.B., Calico Printer.
- Heywood, J. G., 127, Sutherland Avenue, Maiba Vale, London, W., Analytical Chemist.
- Heywood, J. H., Sparth Cottage, Manchester Road, Rochdale, Technical Chemist.
- Heywood, J. S., 7, Caledonian Road, King's Cross, London, N., Chemical Manufacturer.
- Hibbert, W., 14, Goldhurst Terrace, South Hampstead, N.W., Analytical Chemist.
- Hicks, Jas. A., c/o B. Redwood, 4, Bishopsgate Street Within, London, E.C., Analytical Chemist.
- Higgin, W. H., Hopefield, Bolton-le-Moors, Chemical Manufacturer.
- Higgins, C. L., c/o United Alkali Co., Lim., Muspratt's Works, Widnes; and (Journals) 79, Bedford Street South, Liverpool, Manufacturing Chemist.
- Hill, Frank, 52, Water Street, New York, U.S.A., Manufacturing Chemist.
- Hill, J. K., Fullarton Cottage, Irvine, N.B., Manufacturing Chemist.
- Hill, Sydney, 11, Salisbury Street, The Park, Hull, Analytical Chemist.
- Hills, C. H., Anglesea Copper Works, Low Walker, Newcastle-on-Tyne, Copper Smelter.
- Hills, H., Chemical Works, Deptford, London, S.E., Chemical Manufacturer.
- Hills, Harold F., Pine Island Post Office, Kent, Auckland, New Zealand, Analytical Chemist.
- Hills, M. H., Tower Varnish Works, Long Acre, Nechells, Birmingham, Varnish Manufacturer.
- Hills, W., 225, Oxford Street, London, W., Pharmaceutical Chemist.
- Hilton, Edgar G., 37, Kourlandsky Street, St. Petersburg, Russia, Varnish and Paint Manufacturer.
- Hindle, J. H., 8, Cobham Street, Accrington, Dyeworks Manager.
- Hinds, James, 127, Gosford Street, Coventry, Pharmaceutical Chemist.
- Hinman, Bertrand C., c/o Ironclad Manufacturing Co., 186, Cook Street, Brooklyn, E.D., U.S.A., Metallurgical Chemist.
- Hinshelwood, Thos., Glasgow Oil and Paint Works, Glenpark Street, Glasgow, Oil Refiner.
- Hirst, H. Reginald, 1, Marlboro' Villas, Victoria Avenue, Harrogate, Yorks, Works Chemist.
- Hodge, Andrew, Dalmonach Printworks, Alexandria, N.B., Chemist.

- Hodges, Harry B., Southern Railway Co., 1300, Pennsylvania Avenue, Washington, D.C., U.S.A., Chemical Engineer.
- Hodges, J. F., Analytical Chemist.
- Hodgkin, J., 12, Dynevor Road, Richmond, Surrey, Chemical Manufacturer.
- Hodgkinson, J. H., Messrs. E. Potter & Co., Dinting Vale, Glossop, Technical Chemist.
- Hodgkinson, Dr. W. R., 8, Park Villas, Blackheath, S.E. (Journals); and Royal Military Academy, Woolwich, S.E., Prof. of Chemistry.
- Hodgson, C., High House, Epplehy, Darlington, Metallurgical Chemist.
- Hodgson, Wm., 66, Deansgate, Manchester, Oil and Colour Broker.
- Hogben, W., 18, Hunter's Road, Handsworth, Birmingham, Analytical Chemist.
- Hogg, Quintin, 23, Rood Lane, London, E.C., Merchant.
- Hogg, T. W., c/o John Spencer & Sons, Newbarn Steelworks, Newcastle-on-Tyne, Metallurgical Chemist.
- Holden, G. H., Langley Place, Victoria Park, Manchester, Manufacturing Chemist.
- Holgate, S. V., 29, Long Row, Nottingham, Pharmaceutical Chemist.
- Holgate, T. E., 146, Blackburn Road, Darwen, Lancashire, Metallurgist.
- Holgate, T., 12, Hyde Park Road, Halifax, Gas Engineer.
- Holland, Jos., 70, Higher Ardwick, Manchester, Brewer.
- Holland, Philip, 22, Taviston Street, Gordon Square, London, W.C., Analytical Chemist.
- Holland, Philip H., 958, Sherbrooke Street, Montreal, Canada, Merchant.
- Holliday, R. (Read, Holliday & Sons), Huddersfield, Dye Manufacturer.
- Holliday, Thos., Lunnclough Hall, Huddersfield, Aniline Dye, Manufacturer.
- Holloman, Fred R., 396, Barking Road, Plaistow, E., Sugar Works Chemist.
- Holloway, G. T., 57 and 58, Chancery Lane, W.C., Analytical and Consulting Chemist.
- Holloway, Wm., Newlands, Middlesbrough, Manufacturing Chemist.
- Holmes, Ellwood, Wellburn, Jesmond, Newcastle-on-Tyne, Colour Manufacturer.
- Holmes, F. G., 1, Grange Avenue, Chapeltown Road, Leeds, Technical Chemist.
- Holmes, J., 96, Holland Road, Brixton, London, S.W., Analytical Chemist.
- Holt, J. W., North Road, Clayton, near Manchester, Chemical Works Manager.
- Holton, E. C., Sherwin-Williams Co., 100, Canal Street, Cleveland, Ohio, U.S.A., Chemist.
- Holzappel, Max., Quayside, Newcastle-on-Tyne, Manufacturer.
- Homfray, D., 6, Dartmouth Row, Greenwich, S.E., Analytical Chemist.
- Hooker, Benj., Pear Tree Court, Farringdon Road, London, E.C., Mechanical Engineer.
- Hooper, E. G., The Laboratory, Somerset House, London, W.C., Analytical Chemist.
- Hooper, Ernest F., Wear Fuel Works, Herdon Dock, Sunderland, Technical Chemist.
- Hope, Jas., The Nickel Co., Kirkintilloch, N.B., Nickel Works Manager.
- Hopkin, W. K., Fernbrae, Brondesbury Park, N.W., Chemical Manufacturer.
- Hopkins, Erastus, Post Office Box 530, Rumford Falls, Maine, U.S.A., Chemist.
- Hopkins, Gerald V. (Journal), Estable Bella Vista, Fondecion y Beneficiadora, Antofagasta, Chili; and (subscription) Nicholaston House, Penmaen, near Swansea, Metallurgist.
- Hopkins, Herbert W., 13, Harrington Gardens, South Kensington, S.W., Metallurgist.
- Hopkinson, John, Marion Street, Lister Hills, Bradford, Yorks, Lubricant Manufacturer.
- Horn, Wm., Lantaro Nitrate Co., Taltal, Chili, Technical Chemist.
- Horn, W. Freeman, Wandle Colour Works, South Street, Wandsworth, S.W., Varnish, Paint, and Printing Ink Manufacturer.
- Horne, W. D., Yonkers, N.Y., U.S.A., Consulting Chemist.
- Horner, Jarvis W., 27, Brookfield Road, Sheffield, Analyst.
- Horrocks, W. A., 5, Egerton Avenue, Urmston, near Manchester, Bleacher and Finisher.
- Horsman, Fred., 78, Ham Park Road, Forest Gate, Essex, Chemist.
- Horton, William, 38, Belvidere Road, Prince's Park, Liverpool, Analytical Chemist.
- Hosie, G. H., Davidson Place, Innellan, Argyllshire, Technical Chemist.
- Hoskins, A. Percy, 25, Cromwell Road, Belfast, Analytical Chemist.
- Houston, John, 14, Charlotte Street, Manchester, Dry-salter.
- Houston, Robt. S., Briar Villa, Greenlaw Drive, Paisley, N.B., Analytical Chemist.
- Howenden, Fred., Glenlen, Thulow Park Road, West Dulwich, S.E.
- Howard, A. G., Holmbury, Woolford, Essex, Chemical Manufacturer.
- Howard, D., Devon House, Buckhurst Hill, Essex, Chemical Manufacturer.
- Howard, D. L., City Mills, Stratford, London, E., Chemical Manufacturer.
- Howard, W. D., City Mills, Stratford, London, E., Chemical Manufacturer.
- Howorth, Franklin W., c/o Lloyd Wise, 46, Lincoln's Inn Fields, W.C., Manufacturing Chemist.
- Hughes, J., 72, Mark Lane, London, E.C., Agricultural Chemist.
- Hughes, T., 31, London Square, Cardiff, Analytical Chemist.
- Hulme, J., Newton Chemical Works, Hyde, Manchester, Analytical Chemist.
- Humphrey, Chas., Winnington Park, Northwich, Alkali Works Manager.
- Hummel, Prof. J. J., 152, Woodsley Road, Leeds, Prof. of Dyeing.
- Humphrys, N. H., Gasworks, Salisbury, Wilts, Gas Engineer.
- Hunnicke, H. Aug., 1219, Mississippi Avenue, St. Louis, Mo., U.S.A., Adjunct Prof. of Applied Chemistry.
- Hunt, Bertram, P.O. Box 1606, Denver, Col., U.S.A., Technical Chemist.
- Hunt, C., Gasworks, Windsor Street, Birmingham, Gas Engineer.
- Hunt, E., Wood Green, Wednesbury, Staffordshire, Chemical Manufacturer.
- Hunt, F. J., Bow Bridge Soap Works, Stratford, E., Soap Manufacturer.
- Hunt, J. S., Appleton, Widnes.
- Hunt, L. W., Caulton Terrace, Whalley Range, Manchester, Paint and Colour Manufacturer.
- Hunt, W., Hampton House, Wednesbury, Staffordshire, Chemical Manufacturer.
- Hunter, Prof. Matthew, Rangoon College, Rangoon, Burma, Prof. of Chemistry.
- Hunter, Sidney H., 202, Bow Road, E., Mechanical Engineer.
- Huntington, Prof. A. K., King's College, Strand, London, W.C., Prof. of Metallurgy.
- Huntton, Henry, Greystone, Carlton, Ferryhill, co. Durham, Chemist.
- Hunzinger, A., Dinting Vale Printworks, Dinting, Derbyshire, Calico Printer.
- Hurry, E. H., Atlas Cement Co., 143, Liberty Street, New York, U.S.A., Mechanical Engineer.
- Hurst, G. H., 22, Blackfriars Street, Salford, Manchester, Analytical Chemist.
- Hurter, Dr. F., Widnes; and (Journals) Holly Lodge, Cressington Park, Liverpool, Technical Director (United Alkali Co.).
- Huskisson, P. L., 77, Swinton Street, London, W.C., Chemical Manufacturer.
- Huson, C. W., 5, York Buildings, Dale Street, Liverpool, Analytical Chemist.

- Hutcheson, Jno. F., 22, St. Enoch Square, Glasgow, Chemical Manufacturer.
- Hutchinson, C. C., Engineering Works, Carpenter's Road, Stratford, E., Chemical Engineer.
- Hutchinson, Chas. H., Falcon Works, Sackville Street, Barnsley, Yorkshire, Gas Engineer.
- Hutchinson, T. J., Aden House, Manchester Road, Bury, Analytical and Consulting Chemist.
- Hutton-Moss, F. R., 32, Selborne Road, West Brighton, Chemist and Assayer.
- Huxley, J. H., 15, Kenwood Park Road, Sharrow, Sheffield, Metallurgical Chemist.
- I
- Idris, T. H. W., Pratt Street, Camden Town, N.W., Mineral Water Manufacturer.
- Imray, Harold, The Grange, Underhill, New Barnet, Patent Agent.
- Ince, Dr. Walter H., Government Laboratory, Port of Spain, Trinidad, Analytical Chemist.
- Ingle, Dr. Harry, Technical School, Bond Street, Hull, Organic Chemist.
- Ingle, Herbert, Yorkshire College, Leeds, Assistant Lecturer on Chemistry.
- Inglis, R. A., Culrain, Bothwell, N.B., Analytical Chemist.
- Innes, Murray, c/o Old Dominion Copper Co., Globe, Arizona, U.S.A., Technical Chemist.
- Iriyè, Koremasa, China and Japan Trading Co., Kobe, Japan, Analytical Chemist.
- Irvine, R., Royston, Granton, Edinburgh, Chemical Manufacturer.
- Iring, J. M., 17A, Dickinson Street, Cooper Street, Manchester, Chemical Merchant.
- Irwin, W., 3, Wilton Polygon, Cheetham Hill, Manchester, Analytical Chemist.
- Isaac, J. F. V., 114, Marine Parade, Brighton, Research Chemist.
- Isaac, T. W. Player, 114, Marine Parade, Brighton, Chairman of Water Works Co.
- Isaacs, Louis A., 180, Belsize Road, West Hampstead, N.W., Manufacturer.
- Isler, Otto, 35-37, Dickinson Street, Manchester, Chemical Merchant.
- Ivatts, Harold E., 27, Wellington Square, Chelsea, S.W., Analytical Chemist.
- J
- Jackman, E. J., 86, Brooke Road, Stoke Newington, N.E., Technical Chemist.
- Jackson, Edgar, 106, Queen Victoria Street, London, E.C., Analytical and Consulting Chemist.
- Jackson, Edward, Ashleigh, Beaufort Road, Edgbaston, Birmingham, Alkali Works Inspector.
- Jackson, F., Spring Bank, Crumpsall Lane, Manchester, Chemical Apparatus Maker.
- Jackson, Frederick, 10, Half Moon Street, Manchester, Laboratory Furnisher.
- Jackson, G. B., 6, Booth Street, Piccadilly, Manchester, Chemical Manufacturer.
- Jackson, Jas., Dominion Cotton Mills Co., Magog, Quebec, Canada —
- Jackson, John, 98, Dobbie's Loan, Glasgow, Lubricant Manufacturer.
- Jackson, R. V., c/o Scotch and Irish Oxygen Co., Polmadie, Glasgow, Technical Chemist.
- Jackson, Robt., 18, Harrington Street, Dublin, Analytical Chemist.
- Jackson, Saml., c/o Messrs. Binny & Co., Madras, India, Analytical Chemist.
- Jackson, T., Clayton, near Manchester, Chemical Manufacturer.
- Jackson, Walter, 24, Sydenham Avenue, Sefton Park, Liverpool, Metallurgical Chemist.
- Jackson, Rt. Hon. W. L., M.P., F.R.S., 27, Cadogan Square, S.W.; and (Journals) Allerton Hall, Chapel Allerton, near Leeds, Leather Manufacturer.
- Jackson, W. P., Saxilby, near Lincoln, Chemical Works Manager.
- Jago, Wm., 32, Clarendon Villas, Brighton, Chemical Engineer.
- James, Alf., Cassel Gold Extracting Co., 108A, Hope Street, Glasgow, Mining Engineer.
- James, E. T., British Alizarin Co., Ltd., Silvertown, Victoria Docks, E., Secretary.
- James, J. Herniman, Assay Office, Swansea, Assayer.
- James, Dr. J. Wm., Aylmer House, Weston-super-Mare; and (Journals) 29, Redcliff Street, Bristol, Chemical Lecturer.
- James, Lawrence S., 32, Hawley Street, Boston, Mass., U.S.A., Gas Inspector.
- Jameson, A. H., Cleveland Linseed Oil Co., South Chicago, Ill., U.S.A., Chemist.
- Jantzen, Paul, 132, Fenchurch Street, London, E.C., Chemical Merchant.
- Japp, Dr. F. R., F.R.S., The University, Aberdeen, Professor of Chemistry.
- Jarmain, George, 9, York Place, Huddersfield, Analytical Chemist.
- Jarmain, Geo. S., Minerva Works, Turnbridge, Huddersfield, Wool Extractor.
- Jarmay, G., Hartford Lodge, Hartford, Cheshire, Alkali Manufacturer.
- Jarrett, H. T., 90, William Street, New York, U.S.A., Chemist.
- Jarves, Deming, Michigan Carbon Works, Detroit, Mich., U.S.A., Manufacturing Chemist.
- Jarvis, Talbot McL., c/o Ind., Coope, and Co., Ltd., Burton-on-Trent, Brewer.
- Jayne, Dr. H. W., Chem. Lab., Bermuda Street, Frankford, Philadelphia, U.S.A., Analytical Chemist.
- Jekyll, J., Castle Moat House, Lincoln, Chemical Manufacturer.
- Jenkin, W. A., 24, Bella Vista, Minas de Rio Tinto, Provincia de Huelva, Spain, Metallurgical Chemist.
- Jenkins, John H. B., Laboratory, G.E.R. Works, Stratford, E., Analytical Chemist.
- Jenkins, Thos., Bella Vista, Port Talbot, South Wales, Technical Chemist.
- Jenks, Robt. L., Research Department, Imperial Institute, London, S.W., Chemist.
- Jenner, E., 209, Markhouse Road, Walthamstow, Essex, Chemical Manufacturer.
- Jennison, F. H., Craighall Chemical Works, Maryhill, Glasgow, Dyer.
- Johnson, A. E., 1, Eagle Villas, Penn Fields, Wolverhampton, Analytical Chemist.
- Johnson, Chas. H., jr., Laboratory, Rubberine Works, Oatlands Mill, Leeds, Works Manager.
- Johnson, Edmund E., The Warren Hill, Loughton, Essex, Chemical Engineer.
- Johnson, A. E., 40, Idmiston Road, Stratford, London, E., Manufacturing Chemist.
- Johnson, J. Grove, 23, Cross Street, Finsbury, London, E.C., Assayer.
- Johnson, J. Henry, Mountains, Tunbridge, Kent, Patent Agent.
- Johnson, Jesse F., c/o Hamilton Powder Co., Montreal, Canada, Chemical Engineer.
- Johnson, S. H., Warren Hill House, Loughton, Essex, Chemical Engineer.
- Johnson, T. A., Field House, Winton Park, Northwich, Cheshire.
- Johnston, Alex. R., 370, North Woodside Road, Glasgow, Analytical Chemist.
- Johnston, G. L., Kingswood Road, Sydenham Hill, S.E., Secretary.
- Johnston, Thos., Nobel's Explosives Co., Ltd., 149, West George Street, Glasgow, Explosives Co.'s Manager.

Johnston, Wm. A., The S.S. White Dental Manufacturing Co., Princess Bay, New York, U.S.A., Dental Enamel Manufacturer.

Johnston, Wm. E., Kingswood Road, Sydenham Hill, S.E., Assistant Chemist (Bovril, Limited).

Johnston, Wm. G., Chemical Works, Coatbridge Street, Port Dundas, Glasgow, Technical Chemist.

Johnston, W. G., Warwicks' and Richardsons' Brewery, Newark-on-Trent, Chemist.

Johnstone, Jas., Shawfield Works, Rutherglen, Glasgow, Technical Chemist.

Johnstone, Dr. W., Edinham House, Arundel Street, Strand, W.C., Analytical Chemist.

Jones, A. F. Syers, Iquique, Chile, "Nitrate" Manufacturer.

Jones, Chapman, Royal College of Science, South Kensington, S.W., Senior Demonstrator in Chemistry.

Jones, David S., c/o The Lisbon Berlyn Co., Ltd., Pilgrim's Rest, Lydenburg, S.A.R., Analytical Chemist.

Jones, Prof. D. E., Conway Road, Cardiff, Director of Technical Instruction.

Jones, E. W. T., 10, Victoria Street, Wolverhampton, Analytical Chemist.

Jones, Herbert, *see* Sefton-Jones, H.

Jones, John Arthur, Gijon, Spain, Mining Engineer.

Jones, M. W., 50, Mayfield Road, Whalley Range, Manchester, Chemist.

Jones, T. Tolley, 356, Little Collins Street, Melbourne, Victoria, Explosives Manufacturer.

Jones, W. Norris, Lancashire Metal Works, Widnes, Technical Chemist.

Joseland, Walter H., Talk-o'-th'-Hill, near Stoke-on-Trent, Manager of Chemical Works.

Joslin, Omar T., 505, West 157th Street, New York City, U.S.A., Chemical Engineer.

Jouët, Dr. C. H., Roselle, Union Co., N.J., U.S.A., Technical Chemist.

Journaud, Louis, Ste. Colombe-lz-Vienne, Rhône, France, Technical Chemist.

Joy, Douglas G., Sealecoates Oil Mill, Hull, Oil Refiner.

Joyson, F., Killamash, near Rotherham, Yorks, Metallurgical Chemist.

Julien, Alfred, Société des Peintures Sous-marines, 17, Rue Beauvan, Marseilles, France, Civil Engineer.

Jürgensen, Dr. Rolof, Smetanka, 6, Weinberge, Prague, Austria, Chemist.

Justice, P. M., 14, Southampton Buildings, Chancery Lane, London, W.C., Patent Agent.

K

Kalle, Dr. Wm., Biebrich-am-Rhein, Germany, Colour Manufacturer.

Kathreiner, Franz, Worms a/Rhein, Germany, Technical Chemist.

Kaufmann, Dr. Herbert M., 1325, Franklin Street, Philadelphia, Pa., U.S.A. —

Kawakita, Michitada, Kant Strasse 24III, Charlottenburg, Berlin, Analytical Chemist.

Kay, H. A., 71, Maida Vale, London, W. —

Kay, Dr. Percy, West London Polytechnic, Manresa Road, Chelsea, S.W., Analytical Chemist.

Kay, W. E., Gowanbank, Busby, near Glasgow, Printworks Chemist.

Kearns, H. W., Baxenden, near Acerrington, Dyer.

Kebler, Lyman F., 305, Cherry Street, Philadelphia, Pa., U.S.A., Manufacturing Chemist.

Keiser, E. H., Bryn Mawr College, Bryn Mawr, Pa., U.S.A., Professor of Chemistry.

Kellie, Jas. M., Straiton Oil Works, Loanhead, near Edinburgh, Technical Chemist.

Kellner, Dr. Wm., 13, Victoria Road, Old Charlton, S.E., Chemist to War Department.

Kempson, John F., Pye Bridge Chemical Works, near Alfreton, Derbyshire, Chemical Manufacturer.

Kennedy, Louis E., Fanwood, Union Co., N.J., U.S.A., Cement Manufacturer.

Kennedy, Wm., 28, Royal Exchange Square, Glasgow, Oil Works Director.

Kenrick, Prof. Edgar B., St. John's College, Winnipeg, Manitoba, Canada, Professor of Chemistry.

Kent, Wm. J., Assayer and Chemical Engineer.

Kenyon, Thos., The Shrubbery, Hilton Park, Prestwich, near Manchester, Manufacturing Chemist.

Ker, Alan D., Millburn Chemical Works, Garngad Hill, Glasgow, Chemical Manufacturer.

Kerr, Jas., c/o Linlithgow Oil Co., Ltd., Linlithgow, N.B., Works Chemist.

Kerr, Saml. T., c/o Alex. Kerr Bros. & Co., Philadelphia, Pa., U.S.A., Salt Manufacturer.

Kershaw, J., Grease, Varnish, and Cement Works, Hollinwood, near Oldham, Varnish Manufacturer.

Kestner, Paul, 40, Boulevard Vauban, Lille, France, Chemist.

Keys, W. H., Hall End Chemical Works, West Bromwich, Oil and Chemical Manufacturer.

Kibble, W. Oakes, Norton Villa, Buckhurst Hill, Essex, Chemical Engineer.

Kinch, E., Royal Agricultural College, Cirencester, Professor of Chemistry.

King, A. J., Ingersley Vale, Bollington, near Macclesfield, Bleacher and Finisher.

King, C. M., Chemical Engineer.

King, C. M., Campsie Alum Works, Lennoxtown, N.B., Alum Manufacturer.

King, Sir James, Bart., 115, Wellington Street, Glasgow, Chemical Manufacturer.

King, Jas. E., Dominion Cotton Mills, Magog, P.Q., Canada, Printworks Chemist.

King, J. Falconer, Russell Place, Edinburgh, N.B., Consulting Chemist.

King, J. T., Clayton Square, Liverpool, Patent Agent.

King, Robt., 115, Wellington Street, Glasgow, Chemical Manufacturer.

King, Sidney J., 47, Arundel Square, Barnsbury, N., Colour and Dyestuff Traveller.

King, Walter R., 55, Sunderland Road, Forest Hill, S.E., Chemical Manufacturer.

King, W. Grant, The Barber Asphalt Paving Co., 178, Walden Avenue, Buffalo, N.Y., U.S.A., Chemical Engineer.

Kingsford, T. P., Oswego, New York, U.S.A., Starch Manufacturer.

Kingzett, C. T., Elmstead Knoll, Chislehurst, Kent, Technical Chemist.

Kinnicutt, Professor L. P., 77, Elm Street, Worcester, Mass., U.S.A., Professor of Chemistry (Worcester Polytechnic Institute).

Kirkman, R., Landore Alkali Works, Swansea, Alkali Works Manager.

Kirkpatrick, A. J., 179, West George Street, Glasgow, Chemical Merchant.

Kitamura, Y. (Journals), c/o R. Fujihana, Yokoyamacho Sancho, Tokyo, Japan, Agricultural Chemist.

Kitchen, Theo. (Journals), 28, Flinders Lane North, Melbourne, Australia; and (subs.) 35, Queen Victoria Street, E.C., Soap and Candle Manufacturer.

Kitson, Sir James, Bart., M.P., Gledhow Hall, Leeds, Iron and Steel Manufacturer.

Kitto, R., 26, Lancaster Road, Finchbury Park, London, N., Analytical Chemist.

Kleemann, Dr. S., 81, Shrewsbury Road, Old Trafford, Manchester, Analytical Chemist.

Klipstein, A., 122, Pearl Street, New York, U.S.A. (P.O. Box 2833), Chemical Manufacturer and Importer.

Klonowski, W. T. von, P.O. Box 64, Kragerdorp, S.A.R., Chemist and Druggist.

Knaggs, Alfred B., Bradley Lane, Huddersfield, Technical Chemist in Dyeworks.

Knecht, Dr. E., Station Road, Crumpsall, Manchester, Analytical Chemist.

Knight, A. H., 2, Gerald Road, Oxtou, Cheshire, Assayer.

Knight, Henry, 33, Faraday Street, Breck Road, Liverpool, Colour and Varnish Manufacturer.
 Knight, J. B., Silvertown Soapworks, Silvertown, London, E., Soap Manufacturer.
 Knight, J. J., 13, Grafton Street, West Gorton, near Manchester, Technical Chemist.
 Knight, Wm. A., Sexey's Trade School, Bruton, Somerset, Head Master.
 Knights, J. West, County Laboratory, 1, Sidney Street, Cambridge, Analytical Chemist.
 Knipier, F., c/o R. Harper and Co., 352, Flinders Lane, Melbourne, Victoria, Starch Manufacturer.
 Knowles, Joshua, Stormer Hill, Tottington, near Bury, Calico Printer.
 Knox, E. W., Colonial Sugar Refining Co., Sydney, N.S.W.; and c/o Parbury Henry & Co., 7, East India Avenue, London, E.C., Sugarworks Chemist.
 Koechlin, Horace, 19, Avenue du Mont Riboudet, Rouen, France; and (subs.) c/o Koechlin, Baumgartner and Co., 79½, Watling Street, E.C., Chemical Manufacturer.
 Kohn, Dr. Chas. A., University College, Brownlow Street, Liverpool, Chemical Demonstrator.
 Kolb, J., Soc. Anon. des Manuf. de Produits Chimiques, Lille, France, Chemical Manufacturer.
 Koningh, L. de, 325, Kennington Road, S.E., Analytical Chemist.
 Kraftmeier, E., 55, Charing Cross, London, S.W., Explosives Manufacturer.
 Krause, Dr. Albert H., 63, Mueller Avenue, Cleveland, Ohio, U.S.A., Chemist (Grasselli Chemical Co.).
 Krause, Dr. G., "Chemiker-Zeitung," Cöthen, Germany, Editor.
 Krause, O. H., c/o American Sugar Refining Co., Jersey City, N.J., U.S.A., Chemical Engineer.
 Krohn, F. W. T., 3, Minton Villas, Harrow, Technical Chemist.
 Kühl, W. H., 73, Jägerstrasse, Berlin, Germany, Bookseller.
 Kunheim, Dr. Hugo, 32, Doratheenstrasse, Berlin, Chemical Manufacturer.
 Kupferberg, Dr. H., 303, Collyhurst Road, Manchester, Technical Chemist.
 Kveclit, Victor, 79, Murray Street, New York, U.S.A., Dye Merchant.
 Kynaston, J. W., 3, Oak Terrace, Beech Street, Liverpool, Chemical Engineer.

L

Lacey, E. C., 121, Knight's Hill Road, West Norwood, Surrey, Manufacturing Chemist.
 Lacey, T. S., Gas Light and Coke Company, Lupus Street, Pimlico, S.W., Gas Engineer.
 Lagerwall, Dr. Ivar, 63, Rue de Provence, Paris, Petroleum Manufacturer.
 Laidler, C. P., 26, Noble Terrace, Gateshead-on-Tyne, Analytical Chemist.
 Laidler, T. S., Allhusen's Works, Gateshead; and (Journals) 3, Stratford Villas, West Heaton, Newcastle, Analytical Chemist.
 Laing, Jno., 3, Mentone Terrace, Edinburgh, Analytical Chemist.
 Laing, Wm., 224, Swan Arcade, Bradford, Yorks, Oil Merchant.
 Lake, G. jun., 83, Primrose Lane, Glossop, Derbyshire, Analytical Chemist.
 Lambert, Alan, Union Oil Mills, Ltd., 18, Bishopsgate Street Within, E.C., Oil Mills Director.
 Lancaster, Jno. C., 12, Player Street, Alfreton Road, Nottingham, Engineering Works Manager.
 Lander, Albert H., 7, Carlyle Road, Edgbaston, Birmingham, Metal Merchant.
 Landin, John, 49, Drottninggatan, Stockholm, Sweden, Public Analyst.

Lane, Howard, 188, Corporation Street, Birmingham, Consulting Mechanical Engineer.
 Lang, Jas. G., 5, Viewfield Terrace, Hillhead, Glasgow, Analytical Chemist.
 Langbeek, H. W., The Park, Loughton, Essex, Technical Chemist.
 Langdon, Dr. M. J., 15, Dickinson Street, Manchester, Analytical Chemist.
 Lange, Dr. Martin, Westerdokstraat, 25, Amsterdam, Holland, Analytical Chemist.
 Laugen, H. G., Maschinenfabrik, Grevenbroich, Grevenbisich, Germany, Chemical Engineer.
 Langer, Dr. Carl, 15, Brodrick Road, Upper Tooting, S.W., Analytical Chemist.
 Langrick, Thos. E., 2, Bonnington Terrace, Edinburgh, Paint Works Manager.
 Larkin, T., St. Bede Chemical Works, South Shields, Chemical Works Manager.
 Larned, J. N., Young Men's Library, Buffalo, N.Y., U.S.A., Librarian.
 Laseelles, Jno. H., P.O., Calcutta, India, Chemist.
 Lassing, Henry, M.D., 19, Park Place, New York, U.S.A., Editor and Leather Manufacturer.
 Latham, Baldwin, 13, Victoria Street, Westminster, S.W., Civil Engineer.
 Latham, J. J., 157, Albert Road, Appleton, Widnes, Chemical Works Manager.
 Lawrance, H. A., 31, Castle Street, Cape Town, South Africa, Analytical Chemist.
 Lawrence, Jas., Repanno Chemical Co., Paulsboro', N.J., U.S.A., Assistant Superintendent of Works.
 Laws, J. P., 41, Clifton Road, Crouch End, N., Analytical Chemist.
 Lawson, Arthur J., Marsh Soapworks, Bristol, Soap Manufacturer.
 Lawson, Dr. T. A., 114, Alexandra Road, London, N.W., Colour Chemist.
 Lawton, Thos., Calthorpe House, Aldridge Road, Perry Bar, Birmingham, Chemical Works Manager.
 Laycock, Dr. W. F., 2, Park Street, Dewsbury, Analytical Chemist.
 Leach, Walter, 22, St. Andrew's Place, Bradford, Yorks, Analytical Chemist.
 Leather, Dr. J. W., Debra Dun, N.W.P., India, Agricultural Chemist, Government of India.
 Le Bontillier, Clement, c/o Taylor Iron and Steel Co., High Bridge, N.J., U.S.A., Chemist.
 Ledoff, Prof. A., Technological Institute, Kharkoff, Russia, Professor of Chemistry.
 Ledoux, Dr. Albert R., 9, Cliff Street, New York City, U.S.A., Chemist.
 Lee, C. Tennant, 146, Franklin Street, Boston, Mass., U.S.A., Analytical Chemist.
 Lee, J. W. Richmond, 70, St. Helens Gardens, North Kensington, W., Mining Engineer.
 Lee, S. Wright, 6-10, Whitechapel, Liverpool, Wholesale Druggist.
 Lee, Theo. H., c/o Messrs. Johnson and Matthey, 78, Hatton Garden, London, E.C., Analytical Chemist.
 Leech, Jno. E., c/o Jas. Lee and Co., 72, Pine Street, New York City, U.S.A., Chemical Merchant.
 Leeds, F. H., 26, East Bank, Stamford Hill, N., Analytical Chemist.
 Leese, Joseph, 3, Lord Street West, Southport.
 Leete, Jos., 19-25, Bermondsey Street, S.E., Lithographic Printer.
 Leffmann, Dr. H., 715, Walnut Street, Philadelphia, Pa., U.S.A., Analytical and Consulting Chemist.
 Leigh, Cecil, Adderley Park Rolling Mills, Birmingham, Technical Chemist.
 Leitch, Jno. W., Milnsbridge Chemical Works, near Huddersfield, Aniline Dye Manufacturer.
 Leids, A. W. H., Bay City, Mich., U.S.A., Technical Chemist.
 Leonard, F., Enfield Lodge, St. John's Road, Blackheath, S.E., Chemical Manufacturer.
 Lennox, Robt. N., Royal Institution, Albemarle Street, London, W., Chemical Demonstrator.

- Leonard, Wm. J., Hope Chemical Works, Hackney Wick, E., Naphtha Distiller.
- Lequin, E., 9, Rue Ste. Cécile, Paris, Director of St. Gobain Glassworks.
- Lesinsky, Jos., 25, East 72nd Street, New York, U.S.A., Manufacturing Chemist.
- Leslie, H. Mackenzie, c/o Mysore G.M. Co., Lim., Oorgaum, Mysore, South India, Chemical Engineer.
- Lester, J. H., 51, Arcade Chambers, St. Mary's Gate, Manchester, Analytical Chemist.
- Lett, Stephen J., 25, Percy Street, Liverpool, Analytical Chemist.
- Lever, Jas. D., Thornton Hough, Cheshire, Soap Manufacturer.
- Lever, Wm. H., Thornton House, Thornton Hough, Cheshire, Soap Manufacturer.
- Levinstein, Ivan, 21, Mioshull Street, Manchester, Colour Manufacturer.
- Lewes, Prof. Vivian B., Royal Naval College, Greenwich, S.E., Professor of Chemistry.
- Lewinton, B., 14, Cleveland Street, Fitzroy Square, London, S.W.
- Lewis, A. E., 86, Tritonville Road, Sandymount, Dublin, Analytical Chemist.
- Lewis, G. T., 505, Provident Buildings, South and Chestnut Streets, Philadelphia, Pa., U.S.A., Merchant.
- Lewkowitsch, Dr. Julius, Lancaster Avenue, Fennel Street, Manchester, Consulting Chemist.
- Lichtenstein, Theodore, Chemical Works, Silvertown, London, E., Manufacturing Chemist.
- Liddle, G. A., 313, Walmersley Road, Bury, Lancashire, Chemist (E. D. Milnes and Bro., Dyewood Extractors).
- Liddle, W. T., Carr Bank, Walmersley, Bury, Chemist and Manager (Dyewood Extract Works).
- Lidgey, Cecil R., 43, Marmora Road, Honor Oak, S.E., Analyst.
- Liebert, Dr. M., c/o R. Dewhurst and Co., Lim., Birstal, near Leeds, Chemist.
- Liebmann, Dr. A., 61, Marsden Street, Manchester, Analytical Chemist.
- Lightfoot, T. E., 88, Arden Terrace, Acerington, Calico Printer's Chemist.
- Lilly, Oliver M., The Croft, Spondon, Derby, Colour Manufacturer.
- Lindley, Hubert E., Chemical Laboratory, Royal Veterinary College, Camden Town, N.W., Analytical Chemist.
- Ling, Arthur R., 45, Lambton Road, Cottenham Park, Wimbledon, Chemist (Sugar).
- Lishman, W. W. L., Glen Dyeworks, Cornholme, Todmorden, Dyeing Chemist.
- Little, Wm. G., Blendon Grove, Bexley, Kent, Chemical Manufacturer.
- Littlejohn, J., c/o African Banking Corporation, Johannesburg, S.A.R., Analytical Chemist.
- Liversedge, A. J., 45, Scotland Street, Glasgow, Mechanical Engineer.
- Liversidge, Prof. A., F.R.S., The University, Sydney, New South Wales, Professor of Chemistry.
- Livesey, Frank, South Metropolitan Gas Co., 709A, Old Kent Road, London, S.E., Gas Engineer.
- Livingston, W. J., London County Council, Spring Gardens, London, S.W., Analytical Chemist.
- Llewellyn, Geo. H., Pencraig, Caerau Park, Newport, Mon., Solicitor and Science Student.
- Lloyd, Harold T., 1, Hermon Hill, Snaresbrook, N.E., Analytical Chemist.
- Lloyd, Herbert, c/o Electric Storage Battery Co., Drexel Building, Philadelphia, Pa., U.S.A., Chemist and Electrician.
- Lobry de Bruyn, Dr. C. A., 2^e Parkstraat 151, Amsterdam, Holland, Dutch Navy Chemist.
- Lodge, A. S., Newchurch, near Manchester, Technical Chemist.
- Lodge, Edw., 94, Bradford Road, Huddersfield, Teacher of Wool Dyeing.
- Loewenthal, Dr. R., Markustrasse 49, Berlin, O., Textile Chemist and Lecturer on Dyeing.
- Lomas, T., Cleveland, Minehead, Taunton, R.S.O., Chemical Manufacturer.
- Lombard, Emile, 12, Rue Breteuil, Marseilles, France, Director of Pyrites Co.
- Longshaw, Jas., 3, Church Road, Seaforth, near Liverpool, Manufacturing Chemist.
- Lord, F. J., Brooklands, Millbrook, Stalybridge, Analytical Chemist.
- Lorenz, H., 7 and 8, Idol Lane, London, E.C., Chemical Merchant.
- Lorimer, J., Britannia Row, Islington, N., Manufacturing Chemist.
- Lorrain, J. G., Norfolk House, Norfolk Street, Strand, London, W.C., Civil Engineer.
- Losanitsch, Prof. S. M., Belgrade, Servia, Professor of Chemistry.
- Lott, F. E., The Laboratory, Bridge Chambers, Burton-on-Trent, Consulting Brewing Chemist.
- Loughton, J. P., Washington Chemical Works, co. Durham, Technical Chemist.
- Louis, D. A., 77, Shirland Gardens, London, W., Metallurgist and Mining Engineer.
- Louis, Prof. Henry, Durham College of Science, Newcastle-on-Tyne, Professor of Mining.
- Love, Dr. E. G., 80, East 55th Street, New York, U.S.A., Analytical Chemist.
- Lovejoy, Frank W., 170, Chesnut Street, Cambridgeport, Mass., U.S.A., Chemical Engineer.
- Lovibond, J. W., 26, St. Ann's Street, Salisbury, Tintometer Manufacturer.
- Lovibond, T. W., Tyne Brewery, Newcastle-on-Tyne, Brewer.
- Lowe, C. W., Summerfield House, Reddish, near Stockport, Manufacturing Chemist.
- Lowe, Jas. S., c/o Mauritius Estates and Assets Co., Lim., Port Louis, Mauritius, Sugar Planter.
- Lowe, W. F., 2, Hough Green, Chester, Analytical Chemist.
- Lowson, J. G. F., Polton Paper Works, Midlothian, N.B., Paper Maker.
- Lucas, Alf., Government Laboratory, Somerset House, W.C., Analyst.
- Lucas, Bernard R., 32, Ayresome Street, Middlesbrough, Alkali Works Manager.
- Lucas, R., Alwinen-strasse 11, Wiesbaden, Germany, Technical Chemist.
- Luck, A., Powder Mills, Dartford, Kent, Explosives Chemist.
- Luck, E., 68, Sumner Street, Southwark, S.E., Manufacturing Chemist.
- Ludlow, Lionel, c/o Cape Copper Mining Co., O'okiep, Namaqualand, South Africa, Assayer.
- Lund, Jas., 142, Hawthorne Street, Malden, Mass., U.S.A., Ammonia Works Manager.
- Lundholm, Carl O., Ardeer Factory, Stevenston, Ayrshire, Explosives Works Manager.
- Lunge, Dr. G., Englisches Viertel, Hottingen, Zürich, Switzerland, Professor of Chemistry.
- Lungwitz, Emil E., 159, Front Street, New York, U.S.A., Chemist.
- Lungwitz, Theo., c/o Chas. Pfizer and Co., 81, Maiden Lane, New York, U.S.A., Superintending Chemist.
- Lunn, C., Woodsome Lees, Kirkburton, near Huddersfield, Chemical Manufacturer.
- Lupton, Sydney, Grove Cottage, Roundhay, Leeds.
- Luthy, Edmund O., c/o Mellwood Distillery Co., Louisville, Ky., U.S.A., Distiller.
- Lüthy, Otto, 2336, Fairmount Avenue, Philadelphia, Pa., U.S.A., Analytical Chemist.
- Luxmoore, Dr. Chas. M., Harpenden, Herts, Lecturer on Chemistry.
- Lye, W. T., Brachead, Cromwell Road, Luton, Beds, Straw Dyer.
- Lyle, James, Plaistow Wharf, North Woolwich Road, London, E., Sugar Refiner.
- Lyle, Jno., 21, Mincing Lane, London, E.C., Sugar Refiner.
- Lyon, J. G., The Aire Tar Works, Knottingley, Yorks, Tar Distiller.
- Lyte, F. Maxwell, 60, Finborough Road, Redcliffe Square, London, S.W., Chemical Manufacturer.
- Lytle, A. M., North of Ireland Chemical Co., Belfast, Chemical Manufacturer.

M

- Mabery, Prof. Chas. F., 9, Rockwell Street, Cleveland, Ohio, U.S.A., Professor of Chemistry.
- Mabey, Fred O., 195, Anlurth Road, Hackney, N.E., Wine Merchant.
- Macadam, C. T., 116, Fenchurch Street, London, E.C., Manure Works Manager.
- Macadam, Herbert E., 4, Forest Place Villas, Leytonstone, N.E., Manure Works Manager.
- Macadam, Dr. Stevenson, Surgeons' Hall, Edinburgh, Chemical Lecturer and Consulting Chemist.
- Macadam, Prof. W. Ivison, Surgeons' Hall, Edinburgh, Professor of Chemistry and Consulting Chemist.
- Macadam, Stevenson, jun., Surgeons' Hall, Edinburgh, Analytical Chemist.
- McAlister, R., Lawes' Chemical Manure Co., Limited, Barking Creek, Essex, Manure Works Manager.
- McAlley, Robt., Bankside, Falkirk, N.B., Paint Works Manager.
- Macallan, J., 3, Charlemont Terrace, Clontarf, Dublin, Analytical Chemist.
- Macara, Thos., jun., 6, West Bank Terrace, Hillhead, Glasgow, Chemical Student.
- McArthur, Jno., 196, Trinity Road, Wandsworth Common, S.W., Chemist.
- McArthur, J. B., Price's Patent Candle Co., Limited, Bromborough Pool, near Birkenhead, Oil Works Chemist.
- Macarthur, J. G., 98, Dobbie's Loan, Glasgow, Lubricant Manufacturer.
- McArthur, J. S., Cassel Gold Extracting Co., Limited, 108, Hope Street, Glasgow, Technical Chemist.
- McArthur, Thos., Cairnlinn, Kirklee Road, Glasgow, Drysalter and Dyewood Extractor.
- McBretney, E. G., Pontefract Road, Castleford, Yorks, Glass Works Chemist.
- McCallum, J. M., South Park, Paisley, N.B., Soap Manufacturer.
- McCalman, D., Waterside, Irvine, N.B., Technical Chemist.
- McCann, Owen, 532, Old Ford Road, Bow, E., Printing Ink Manufacturer.
- McCombie, C., c/o C. G. Gross and Co., 9, Mincing Lane, London, E.C., Drug and Chemical Merchant.
- McCowan, W., The Brewery, Reading, Berks, Brewer.
- McCulloch, J., Oakleigh, Rose Street, Garnet Hill, Glasgow, Chemical Works Manager.
- McCulloch, Norman, 7, Melrose Street, Glasgow, Analytical Chemist.
- McDaniel, J. J., Bandon, Ireland, Distiller.
- Macdonald, A., 72, Great Clyde Street, Glasgow.
- Macdonald, John, Distillery Offices, Fort William, N.B., Distiller.
- Macdonald, J. W., c/o Messrs. H. Tate & Sons, Love Lane, Liverpool, Analytical Chemist.
- Macdonald, T. M., Wallikabo Estate, St. Vincent, West Indies, Sugar Chemist.
- McDongall, Arthur, Fallowfield House, Fallowfield, Manchester, Chemical Manufacturer.
- McDongall, Isaac, jun., High Bank, Didsbury, Manchester, Student.
- McDongall, Isaac S., High Bank, Didsbury, Manchester, Manufacturing Chemist.
- McDongall, J. T., Dunolly, Morden Road, Blackheath, S.E., Manufacturing Chemist.
- MacEwan, Peter, 4, Gresley Road, Hornsey Lane, N. (Journals); and 42, Cannon Street, E.C.; Editor of "Chemist and Druggist."
- McEwen, Atholl F., 43, Gilmore Road, Lewisham, S.E., Analytical Chemist and Assayer.
- McEwen, Jas., Ruthven House, Bowden Lane, Marple, Cheshire, Aerated Water Engineer.
- Macfarlane, J. A., Santa Rosalia, Baja California, via Guaymas, Mexico, Metallurgical Chemist.
- Macfarlane, R. F., Tharsis Copper Works, East Moors, Cardiff, Technical Chemist.
- Macfarlane, Thos., Inland Revenue Dept., Ottawa, Canada, Analyst to Dominion of Canada.
- Macfarlane, Walter, Garnockside, Glengarnock, R.S.O., N.B., Chemist and Metallurgist.
- McFarlane, Walter D., c/o Canada Paper Co., Craig Street, Montreal, Canada, Paper Manufacturer.
- McFarlane, W. W., 613, East 14th Street, Chester, Pa., U.S.A., Dyeworks Manager.
- McGeorge, A. J. (subs.), 78, Mount Pleasant, Liverpool; and (Journals) 205, West 78th Street, New York City, U.S.A., Analytical Chemist.
- McGhie, T. Burns, 10, St. James', New Cross, S.E., Analytical Chemist and Assayer.
- McGill, Dr. J. T., Vanderbilt University, Nashville, Tenn., U.S.A., Adjunct Professor of Chemistry.
- McGlashan, John, Cawnpore Sugar Works, Cawnpore, India, Technical Chemist.
- McGowan, John, Ash House, Talke, near Stoke-upon-Trent, Colliery Manager.
- Mellwaine, Alf. W., Stoneferry, Hull, Oil Manufacturer.
- MacIndoe, G. D., Alexandra Cottage, Haslett Street, Auckland, New Zealand, Chemical Works Manager.
- MacIntosh, C. J., 54, Leadenhall Street, London, E.C., Chemical Merchant.
- MacKean, Wm., Incandescence Gas Light Co., Ltd., 14, Palmer Street, Westminster, S.W., Technical Chemist.
- McKechnie, D., Eccleston Grange, Prescot, Lancashire, Copper Extractor.
- McKechnie, D. M., Greystone House, Penketh, near Warrington, Copper Extractor.
- McKellar, W. G., c/o United Alkali Co., Ltd., Eglinton Works, Irvine, N.B., Technical Chemist.
- McKenna, Dr. Chas. F., 221, Pearl Street, New York City, U.S.A., Chemist.
- McKenzie, Angus, 52, Water Street, New York, U.S.A., Essential Oils Manufacturer.
- Mackenzie, Dr. G. S., Sydney Smelting Works, Woolwich, N.S.W., Metallurgical Chemist.
- Mackenzie, Robt. W. R., Huntingtowerfield, Perth, N.B., Linen Bleacher.
- Mackenzie, T. E., 4, Ethel Terrace, Mount Florida, Glasgow, Technical Chemist.
- Mackenzie, Dr. W. Cossar, Tewfikieh College of Agriculture, Ghizeh, Egypt, Analytical Chemist.
- McKerrow, C. A., 18, Exchange Street, Manchester, Analytical and Consulting Chemist.
- McKesson, John, 91, Fulton Street, New York City, U.S.A., Manufacturing Chemist.
- Mackey, W. McD., Victoria Chambers, Leeds, Analytical Chemist.
- McKillop, Jno., 4, Galveston Road, Putney, S.W., Metallurgist.
- McKinlay, R. W., Ameliaville, Aytoun Road, Pollokshields, N.B., Metal Merchant.
- Mackinnon, A. K., 12, Popstone Road, South Kensington, S.W.
- MacLean, Alex. S., 31, Bank Street, Greenock, N.B., Soap Refiner.
- McLellan, J. Y., 34, Friedrich Strasse, Bernburg, Anhalt, Germany, Chemical Manufacturer.
- McLeod, Professor H., F.R.S., Cooper's Hill, Staines, Professor of Chemistry.
- McLeod, Jas., Alpine Villa, Cardross Road, Dumbarton, N.B., Analytical Chemist and Gas Examiner.
- Macmillan, Arch., Chemical Laboratory, 29, Chambers Street, Edinburgh.
- McMillan, W. G., Metallurgical Laboratory, Mason College, Birmingham, Metallurgical Chemist.
- McMullan, Chas., 20, Corn Market, Belfast, Ireland, Soap Works Manager.
- McMurtrie, J. M., 21, Princes Street, Pollokshields, Glasgow, Brass Founder.
- McMurtry, G. C., Wallaroo, South Australia, Metallurgist.
- Macnab, C., Lillyburn, Milton of Campsie, N.B., Calico Printer.
- Macnab, W., 14, Great Smith Street, Westminster, S.W., Analytical Chemist.

- Maectear, J., 28, Victoria Street, Westminster, S.W., Chemical Engineer.
- MeVie, Jas. P., Tennant's Works, Hebburn-on-Tyne, Analytical Chemist.
- McVitie, Robt., The St. Andrew Biscuit Works, Edinburgh, Biscuit Manufacturer.

- Mahon, R. W., Monongahela Furnaces, McKeesport, Pa., U.S.A., Analytical Chemist.
- Major, J. Lewis, Senlecoates, Hull, Tar Distiller and Chemical Manufacturer.
- Makin, James, Wallhead Mills, Rochdale, Paper Stainer.
- Mallinekrodt, Edw., Mallinekrodt Chemical Works, St. Louis, Missouri, U.S.A., Manufacturing Chemist.
- Mander, S. T., 17, Gracechurch Street, London, E.C.; and (Journals) Varnish Works, Wolverhampton; Varnish Manufacturer.
- Manbes, P., 3, Rue Sala, Lyons, France, Metallurgical Engineer.
- Mann, Harold H., 16, Aberdeen Place, Maida Vale, N.W., Chemical Research Student.
- Mann, John C., 19, New City Road, Plaistow, E., Chemist.
- Manning, F. A., 18, Billiter Street, London, E.C., Analytical Chemist.
- Manning, Isaac H., Chapel Hill, N.C., U.S.A., Manufacturing Chemist.
- Mannington, H. T., Grove House, Halkyn Street, Flint, North Wales.
- Mansbridge, Wm., 9, The Green, Stratford, E., Chemist.
- Marchlewski, Dr. L., 25, Wellington Street, Higher Broughton, Manchester.
- Markel, Dr. K., Lodge Lane, Warrington, Technical Chemist.
- Markham, A. D., 71, Queen Street, Hull, Pharmaceutical Chemist.
- Marley, J. E., Hebburn-on-Tyne, Iron Founder.
- Marsh, J. T., British Alkali Works, Widnes, Chemist.
- Marsh, W., Union Alkali Co., Soho Works, Manchester, Chemical Manufacturer.
- Marsh, Walter, Mysore West Gold Co., Lim., Oorgaum, Mysore, South India, Engineer.
- Marshall, Arthur, 65, Fairholme Road, West Kensington, W., Chemist.
- Marshall, Dr. Hugh, Chemistry Department, The University, Edinburgh, Professor of Chemistry.
- Marshall, Francis G., 13, Noble Terrace, Darham Road, Gateshead, Technical Chemist.
- Marshall, Jas., Willowbank, Girvan, N.B., Chemical Student.
- Marshall, Jas. Burt, Luncarty, Perth, N.B., Bleacher.
- Marshall, Prof. T. Rymer, St. Mungo's College, Glasgow, Professor of Chemistry.
- Marshall, Wm., 149, Drake Street, Rochdale, Dyer.
- Marshall, Wm. (Journals), c/o D. G. Rose, Samarang, Java; and (subs.) c/o D. R. Calder Marshall, 49, Queen Street, Edinburgh, Analytical Chemist.
- Marshall, Robt., Halliwell Bleachworks, Bolton-le-Moors, Analyst.
- Martin, Alex. M., Douglas Villa, Dunbeth Road, Coatbridge, N.B., Analytical Chemist.
- Martin, Chas. H., 1, Oakfield Terrace, Crescent, Salford, Oil and Soap Works Assistant Manager.
- Martin, H., Poole, near Wellington, Somerset, Manure Works Manager.
- Martin, N. H., 29, Mosley Street, Newcastle-on-Tyne, Manufacturing Chemist.
- Martin, T. Tremills, 45, Stapleton Hall Road, Stroud Green, N., Analytical Chemist.
- Martin, W. H., 183n, King's Road, Chelsea, London, S.W., Analytical Chemist.
- Martindale, Wm., 19, Devonshire Street, Portland Place, W., Pharmaceutical Chemist.
- Martineau, Sydney, South Road, Clapham Park, S.W., Sugar Chemist.
- Martino, F. W., 107, Montgomery Road, Sharrow, Sheffield, German Silver Manufacturer.
- Martius, Dr. C. A., 8, Vosse Strasse, Berlin, Germany, Colour Manufacturer.
- Martyu, T. Graham, 4, The Avenue, Truro, Cornwall, Metallurgist.
- Martyn, W., Afton House, Hebburn-on-Tyne, Chemical Works Manager.
- Mason, A. H., Seabury Buildings, 59-61, Maiden Lane, New York City, U.S.A., Manufacturing Chemist.
- Mason, J., Eynsham Hall, Witney, Oxon, Director of Pyrites Co.
- Mason, J. Francis, Eynsham Hall, Witney, Oxon.
- Mason, Thos., Hyson Green Works, Nottingham, Manufacturing Chemist.
- Mason, W. B., 117, Derby Street, Bolton-le-Moors, Pharmaceutical Chemist.
- Masson, Prof. D. Orme, University of Melbourne, Victoria, Australia, Professor of Chemistry.
- Master, Ardesheer B., 679, Tardeo, Bombay, India, Chemical Manufacturer.
- Mather, Colin, Salford Iron Works, Manchester, Engineer.
- Mather, J., Blaydon Chemical Works, Blaydon-on-Tyne, Manager.
- Matheson, W. J., 178, Front Street, New York, U.S.A., Chemical Merchant.
- Matos, Louis J., 728, Union Street, Philadelphia, Pa., U.S.A., Chemist.
- Matthews, C. G., St. John's Lodge, Beckenham, Kent, Brewing Chemist.
- Mawdsley, W. H., G.P.O., Rockhampton, Queensland, Chemist.
- Maxim, Hud-on, 55, Charing Cross Mansions, London, W.C., Explosives Manufacturer.
- Maxwell, Jno., Solway Chemical Works, Silloth, Cumberland, Chemical Manure Manufacturer.
- Maxwell, Thos., 49, Harvie Street, Bridgeton, Glasgow (Journals); and Mossknowe, Braeside Avenue, Rutherglen, Manufacturing Chemist.
- Mayenfeld, Dr. E. von Salis. See under "Salis."
- Mayer, Dr. Nelson B., 407, North 3rd Street, Philadelphia, Pa., U.S.A., Chemist.
- Mayer, Wm. Turner, c/o Albany Chemical Co., 65-67, Green Street, Albany, N.Y., U.S.A., Manufacturing Chemist.
- Mayfield, H. B., Heanor, near Nottingham, Dyer.
- Mayhew, E. W. A., High Street, Freemantle, Western Australia, Manufacturing Chemist.
- Meacham, Chas. S., Pettridge, Maidstone, Kent, Brewer.
- Mead, Frank, Sutton Gasworks, Surrey, Gas Engineer.
- Meggitt, H. A., Chemical Works, Mansfield, Notts, Manure Manufacturer.
- Meggitt, Loxley, c/o Saml. Meggitt and Sons, Lim., Mansfield, Notts, Analytical Chemist.
- Meikle, Jno., 4, Woodlands Road, Glasgow, Journalist.
- Meldola, Prof. R., F.R.S., 6, Brunswick Square, London, W.C., Professor of Chemistry.
- Meldrum, Jas. Jones, Atlantic Works, City Road, Manchester, Manufacturing Engineer.
- Mellen, Edwin D., c/o Curtis, Davis, & Co., 184, Broadway, Cambridgeport, Mass., U.S.A., Soap Manufacturer.
- Mellon, W. W., 16, Sandymount Road, Dublin, Ireland, Manufacturing Chemist.
- Mellor, S., Magnesium Metal Co., Patricroft, Manchester, Metal Refiner.
- Melville, D., P.O. Box No. 1, Woodmere, Wayne Co., Mich., U.S.A., Chemical Works Manager.
- Mendeleeff, Prof. D., Cadet Line 9, Vassilieff Island, St. Petersburg, Professor of Chemistry.
- Menges, Dr. Franklin, Penna. College, Gettysburg, Pa., U.S.A., Professor of Applied Chemistry.
- Mensching, Dr. C., Crumpsall Vale Works, Blackley, near Manchester, Chemist.
- Menzies, R. C., Inveresk Mills, Musselburgh, N.B., Paper Maker.
- Mercer, C. A., 22, Streathbourne Road, Upper Tooting, S.W., Chemical Apparatus Maker.
- Mercer, J. B., 330, Lower Broughton Road, Manchester.
- Mercer, F. M., 89, Bishopsgate Street, London, E.C., Manufacturing Chemist.

- Mercer, Thos., The Brewery, Edenfield, near Bury, Lancashire, Brewing Chemist.
- Merek, E., Darmstadt, Germany, Manufacturing Chemist.
- Merrell, Geo., Lock Box 786, Cincinnati, Ohio, U.S.A., Manufacturing Chemist.
- Messel, Dr. R., Silvertown, London, E., Chemical Manufacturer.
- Metcalf, Jno., Moorfield, Altham, near Acreington, Tar Distiller.
- Metcalf, Wm., Aspin House, Oswaldtwistle, near Acreington, Tar Distiller.
- Mewburn, J. C., 55 and 56, Chancery Lane, London, W.C., Patent Agent.
- Meyer, Max E., 62, Corso Venezia, Milan, Italy, Chemist.
- Michaelis, G., 292, Lark Street, Albany, N.Y., U.S.A., Chemist and Professor of Pharmacy.
- Milestone, W. C., Garrett Lane, Wandsworth, S.W., Chemical Works Manager.
- Miller, Dr. A. K., Kilvert's Buildings, Withy Grove, Manchester, Analytical Chemist.
- Miller, A. Russell, 28, Lilybank Gardens, Hillhead, Glasgow, Printworks Chemist.
- Miller, E. V., c/o New Zealand Sugar Co., Auckland, New Zealand, Sugar Works Chemist.
- Miller, Geo., Church Cottage, Halewood, Lancashire, Technical Chemist.
- Miller, Dr. Harry E., 1264, 14th Street, Oakland, Cal., U.S.A., Analytical Chemist.
- Miller, Hugh L., 414, North Front Street, Wilmington, North Carolina, U.S.A., Chemist (Navassa Guano Company).
- Miller, Dr. H. von, Beatrixgasse 3201, Vienna, Austria, Chemical Manufacturer.
- Miller, Dr. John A., Niagara University, 203, Ellicott Street, Buffalo, N.Y., U.S.A., Professor of Chemistry.
- Miller, Jno., Messrs. Jas. Black & Co., 11, Exchange Square, Glasgow, Calico Printer.
- Miller, J. Carlile, 89, Rumbold Street, Bridgeton, Glasgow, Manufacturing Chemist.
- Miller, J. Hopkins, 23, McAslin Street, Glasgow, Dyeworks Chemist.
- Miller, Jno. Poynter, Sandilands Chemical Works, Aberdeen, Technical Chemist.
- Miller, Dr. N. H. J., Harpenden, near St. Albans, Agricultural Chemist.
- Miller, T. Paterson, The Cairns, Cambuslang, near Glasgow, Dyer and Printer.
- Miller, W. M., 42, Canning St., Glasgow, Sugar Chemist.
- Mills, Chas., 21, St. Mary Abbott's Terrace, Kensington, W., Chemist to Colour Works.
- Mills, Prof. E. J., F.R.S., 60, John Street, Glasgow, Professor of Chemistry.
- Milner, E., Hartford Manor, Northwich, Alkali Manufacturer.
- Milnes, Edmund, Seedfield, Bury, Lancashire, Dyeing Extract Maker.
- Milnes, J. M., c/o G. C. Whitfield, 1, Hardshaw Street, St. Helens, Chemical Engineer.
- Miner, Harlan S., c/o Welsbach Light Co., Gloucester City, N.J., U.S.A., Technical Chemist.
- Miniati, T., Penketh, near Warrington, Chemist.
- Mistovski, Louis, Broadfield Rubber Works, Heywood, near Manchester, Manager.
- Mitchell, Chas. A., 11, Hubert's Grove, Clapham, S.W., Analyst.
- Mitchell, J. W., Wood Leigh, Clough Fold, near Manchester, Waste Bleacher.
- Mitchell, Ralph, The Cedars, 4, Augustus Road, Edgbaston, Birmingham, Chemical Student.
- Mitchell, Robt., 14, Marchhall Road, Edinburgh, Gas Engineer.
- Mitting, E. K., 416, Huron Street, Chicago, Ill., U.S., Chemical Manufacturer.
- Moale, Philip R., c/o New York and Boston Dyewood Co., Greenpoint, Brooklyn, N.Y., U.S.A., Analytical Chemist.
- Moffatt-Johnston, J., The Birches, Midealder, N.B., Chemist.
- Mohr, Dr. B., 69A, Parliament Hill, Hampstead, N.W., Consulting Chemist and Metallurgist.
- Mole, Herbert B., 2, Town St., Shepton Mallet, Somerset, Brewer.
- Molineux, John, C.B., Selsley House, Albert Road, Battersea, S.W., Inland Revenue Inspector.
- Molineux, Roland, 6-8, Jersey Street, Newark, N.J., U.S.A., Colour Work Chemist and Manager.
- Moucrieff, John, Elmside, Balhousie, Perth, N.B., Glass and Ink Manufacturer.
- Mond, L., F.R.S., 20, Avenue Road, Regent's Park, London, N.W.; and 64, Via Sistina, Rome, Alkali Manufacturer.
- Mond, Robt. L., Winnington Hall, Northwich, Chemist.
- Moodie, W. E., Croftingea Works, Alexandria, N.B., Analytical Chemist.
- Moody, Samuel J., Casilla 988, Buenos Ayres, Argentina, Chemical Manufacturer.
- Mook, Chas., Douglasshall, Westeregela, Magdeburg, Germany, Alkali Works Director.
- Mooney, M., Chemical Works, 74, Rogerson's Quay, Dublin, Chemical Manufacturer.
- Moore, B. T., Longwood, Bexley, Kent, Civil Engineer.
- Moore, Chas. C., 11, Old Hall Street, Liverpool, Chemist.
- Moore, Dr. Geo. D., 25, Catherine Street, Worcester, Mass., U.S.A., Professor of Chemistry.
- Moore, R. T., 156, St. Vincent Street, Glasgow, Mining Engineer.
- Moore, Thos., "Le Nickel," Noumea, New Caledonia, Analytical Chemist.
- Moore, Thos., Northwich, Cheshire, Merchant.
- Moore, Wm. F., Lonsdale, Temple Road, Upper Rathmines, Dublin, Wholesale Druggist.
- Moorhouse, J. B., Cecil Mount, Horton Park, Bradford, Dyer.
- Mordle, F. Dare, Fishpond Drive, The Park, Nottingham, Starch Manufacturer.
- Morgan, Albert J., 439, West Street, New York City, U.S.A., Soap Manufacturer.
- Morgan, J. R., Brogini, Avenue Road, Highgate, N., East India Merchant.
- Morgan, Jno. Jas., Riverdale, Abergavenny, Assayer.
- Morgaus, Thos., The Guildhall, Bristol, Civil Engineer.
- Morison, J. Gillies, Aberfoyle, 5, Birdharst Road, South Croydon, Chemist.
- Moritz, Dr. E. R., 72, Chancery Lane, London, W.C., Brewing Chemist.
- Morley, Dr. H. Forster, 47, Broadhurst Gardens, South Hampstead, N.W., Professor of Chemist.
- Morrell, Jno. B., Holdgate House, York, Cocoa Manufacturer.
- Morrice, Jas. A., 1, Athole Gardens Place, Kelvinside, Glasgow, Starch and Gum Manufacturer.
- Morris, Dr. G. Harris, 72, Chancery Lane, London, W.C. (Journals), 18, Gwendyr Road, West Kensington, W., Brewing Chemist.
- Morris, Herbert N., 52, Manley Road, Manchester, Technical Chemist.
- Morris, J. H., 63 and 65, Blundell Street, Liverpool, Chemist.
- Morris, R., Doncaster, Chemical Manufacturer.
- Morrison, Geo. R., Richmond House, Plaistow, Essex, Analytical Chemist.
- Morrison, J., St. Peter's Chemical Works, Newcastle-on-Tyne, Chemical Engineer.
- Morson, T., 124, Southampton Row, Russell Square, London, W.C., Manufacturing Chemist.
- Morton, Jas., Dalquhurn Works, Renton, N.B., Dyeworks Manager.
- Mosenthal, Henry de, 220, Winchester House, Old Broad Street, London, E.C., Explosives Company Manager.
- Moss, J., Wilson Street, New Cross Road, London, S.E., Manufacturing Chemist.
- Moul, Frank, Aldersgate Chemical Works, Southall, Technical Chemist.
- Moult, J., Underhill, Low Fell, Gateshead-on-Tyne, Secretary.
- Moulton, G. I., Solo Mills, Macclesfield, Chemical Manufacturer.
- Mount, Edw., Oaklands, Aughton, near Ormskirk, Assistant Secretary (United Alkali Company).

Muir, J. P., 233, Camden Road, London, N.W., Chemist.
 Muir, Jas. Stanley, Chemical Laboratory, The University, Glasgow; (Journals) to 27, Huntley Gardens, Kelvinside, Glasgow, Chemical Demonstrator.
 Muir-Smith, W., Carolina Port, Dundee, Manager of Dundee Oil Works.
 Müller, Geo., P.O. Box 486, Colorado Springs, Col., U.S.A., Chemist.
 Müller, Dr. H., F.R.S., 13, Park Square East, Regent's Park, London, N.W., Research Chemist.
 Munro, Dr. J. M. H., Churchfields, Salisbury, Professor of Chemistry.
 Munroe, Prof. Chas. E., Columbian University, Washington, D.C., U.S.A., Professor of Chemistry and Dean.
 Murdoch, H. R. M., 4, Nobel's Villas, Stevenston, Ayr-shire, Explosives Chemist.
 Muspratt, E. K., Seaforth Hall, near Liverpool, Alkali Manufacturer.
 Muspratt, Max, Seaforth Hall, near Liverpool, Technical Chemist.
 Muspratt, S. K., 24, Grove Park, Liverpool, Alkali Manufacturer.
 Muter, Dr. J., Winchester House, Kennington Road, London, S.E., Chemical Lecturer.
 Muurling, T. J. R., 77, William Street, New York City, U.S.A. Dye-stuff Importer.
 Myers, Wm. S., 98, Easton Avenue, New Brunswick, N.J., U.S.A., Instructor in Chemistry (New Jersey State Scientific School).

N

Nadieu, Capt. M., 7, Dumskaya, St. Petersburg, Russia, Government Engineer.
 Naef, Dr. P., P.O. Box 473, Kansas City, Mo. U.S.A., Technical Chemist.
 Napier, J., 89, London Road, Ipswich, Chemist.
 Napier, Jas., 15, Princes Square, Strathbungo, Glasgow, Manufacturing Chemist.
 Napier, Jno. W., Chemical Works, Addiewell, N.B., Chemist.
 Nason, Carleton W., 71, Beckman Street, New York, U.S.A., Mechanical Engineer.
 Naylor, Wm., 16, Walton's Parade, Preston, Lancashire, Chief Inspector (Ribble Joint Committee).
 Naylor, W. A. H., 38, Southwark Street, London, S.E., Manufacturing Chemist.
 Neill, Geo. D., 26, Forsyth Street, Greenock, N.B., Sugar Refiner.
 Neilson, James, 107, High John Street, Glasgow, Chemist.
 Neilson, Thos., c/o Utah Furnace and Manufacturing Co., Ogden, Utah, U.S.A., Metallurgical Chemist.
 Neilson, Wm., 23, Terrace Road, Upton Manor, E., Technical Chemist.
 Neiman, H. S., 8, East 97th Street, New York City, U.S.A., Colour Chemist.
 Nelson, Arthur J., c/o Clayton Aniline Co., Ltd., Clayton, Manchester, Chemist.
 Nesbit, Jas., 19, Wellington Street, Portobello, Edinburgh, Chemical Student.
 Ness, T., Black Banks Chemical Works, Darlington, Tar Distiller.
 Newall, F. S., Washington, co. Durham, Chemical Manufacturer.
 Newall, J. F., 8, Market Place, Manchester, Oil Merchant.
 Newberry, Spencer B., Sandusky Portland Cement Co., Sandusky, Ohio, U.S.A., Cement Works Manager.
 Newlands, B. E. R., 27, Mineing Lane, London, E.C., Analytical and Consulting Chemist.
 Newlands, W. P. R., 1, Mildenhall Road, Lower Clapton, N.E., Sugar Chemist.
 Newsholme, G. T. W., 74, Market Place, Sheffield, Pharmaceutical Chemist.

Newton, A. H., Belsize Court, Hampstead, N.W., Artist's Colour Manufacturer.
 Newton, H. C., Knowle House, Brentwood, Essex, Artists' Colour Manufacturer.
 Newton, Jno., Park Green, Macclesfield, Silk Dyer.
 Newton, Jno., Manor Works, Rotherhithe New Road, London, S.E., Manure Manufacturer.
 Nichols, J. A., Stanley Mount, New Mills, near Stockport, Teacher of Science.
 Nichols, W. H., 45—47, Cedar Street, New York, U.S.A., Manufacturing Chemist.
 Nicholson, J. C., Headingley, Leeds, Chemical Manufacturer.
 Nickolls, John B., The Laboratory, Grange, Guernsey, Analytical Chemist.
 Nicol, Dr. W. W. J., 15, Blacket Place, Edinburgh, Chemical Lecturer.
 Nimmo, J., Penshurst, Stanger Road, South Norwood, S.E., Analytical Chemist.
 Nishigawa, T., Chemical Works, Kawa Kitamura, Osaka, Japan, Works Director.
 Nolting, Dr. E., Ecole de Chimie, Mulhouse, Alsace, Germany, Professor of Chemistry.
 Norman, F. J., Lyndhurst, Higher Runcorn, Cheshire, Chemical Manufacturer.
 Norman, J. T., 78, Chelverton Road, Putney, S.W., Consulting Chemist.
 Norris, Webster, Melrose, Mass., U.S.A., Rubber Works Chemist.
 Norris, Wm. M., Princeton, N.J., U.S.A., Leather Chemist.
 North, E. Gordon N., Bella Vista 14, Minas de Rio Tinto, Huelva, Spain, Technical Chemist.
 Northing, J., The Murrrough, Wicklow, Ireland, Technical Chemist.
 Norton, Dr. S. A., 363, East Town Street, Columbus, Ohio, U.S.A., Professor of Chemistry (Ohio State University).
 Norton, Dr. T. H., University of Cincinnati, Ohio, U.S.A., Professor of Chemistry.
 Nuttall, Harry, c/o Jno. A. Brenner and Co., Albert Street, St. Mary's, Manchester, Oil Manufacturer.

O

Oakes, Geo. A., Bloomfield, N.J., U.S.A., Woollen Mill Owner.
 O'Beirne, W. G., British Chemical Works, Clydebank, Glasgow, Manufacturing Chemist.
 Oddie, Jas., School of Mines, Ballarat, Australia, Chemical Lecturer.
 Oddy, Robert W., 60, Waterhouse, Toad Lane, Rochdale, Chemist.
 Odling, Dr. W., F.R.S., 15, Norham Gardens, Oxford; and 38, Ladbroke Grove Road, North Kensington, W. Professor of Chemistry.
 Oehler, K., Offenbach-am-Main, Germany, Colour Manufacturer.
 Ogata, Saburo, Imperial Mint, Okurasho Branch, Tokyo, Japan, Assayer.
 Ogilvy, D. J., Gest Street; and C. H. and O. R. R., Cincinnati, Ohio, U.S.A., Manufacturing Chemist.
 Ogston, G. H., Junior Athenæum Club, Piccadilly, London, W., Analytical Chemist.
 Ogura, K., Army Survey Department, General Staff, Tokio, Japan, Photographer.
 Oliver, Jas. M., Kirkcaldy, N.B., Engineer.
 Oliver, F., 70, Winchester Street, South Shields, Analytical Chemist.
 Oliver, Wm. Letts, 1066, 12th Street, Oakland, Cal., U.S.A., Mining Engineer.
 Ollerenshaw, S., Kurtz Works, St. Helens, Technical Chemist.
 O'Neill, E. H., Johnson's Saccharum Co., Limited, Stratford, London, E., Managing Director.
 Orme, J., 65, Barbican, London, E.C., Manufacturing Chemist.

- Ormerod, John, Croft Head, Littleboro', near Manchester, Tanner and Currier.
- Orr, A. (subs.), 19, Albion Crescent, Dowanhill, Glasgow; and (Journals) 109, Pitt Street, Sydney, New South Wales, Analytical Chemist.
- Orr, J. B., Blantyre Lodge, Westcombe Park, London, S.E., Chemical Manufacturer.
- Orr, Robert, 8, Great Western Terrace, Glasgow, Manufacturing Chemist.
- Orsman, W. J., Roburite Explosives Co., Gathurst, near Wigan, Explosives Chemist.
- Osmund, Jno. H., c/o Smith, Bell, & Co., Manila; and (Journals) Coniston, North End Avenue, Portsmouth, Sugar Works and Technical Chemist.
- Ostlere, Edward, Messrs. Barry, Ostlere, & Co., Kirkealdy, N.B., Linoleum Manufacturer.
- O'Shea, L. T., Firth College, Sheffield, Chemical Lecturer.
- O'Sullivan, C., F.R.S., 140, High Street, Burton-on-Trent, Brewer and Chemist.
- O'Sullivan, J., 26, Ashby Road, Burton-on-Trent, Brewing Chemist.
- Oswell, Benj. L., 71, Spring Terrace Road, Burton-on-Trent, Brewer's Chemist.
- Oushkoff, P. K., Elabonga, Govt. of Viatka, Russia, Chemical Manufacturer.
- Overend, F. L., Blairlodge School, Polmont Station, N.B., Teacher of Chemistry.
- Overtoun, Lord, 7, West George Street, Glasgow, Chemical Manufacturer.
- Owen, Thos., Henley Grove, Westbury-on-Trym, Bristol.
- Owens, Caradoc, 88, Great Clowes Street, Lower Broughton, Manchester, Dyer's Manager.
- Oxland, Robert, 32, Portland Square, Plymouth, Analytical and Consulting Chemist.
- P**
- Packard, E., jun., Branford, near Ipswich, Manure Manufacturer.
- Page, F. J. M., 54, Sutherland Street, Pimlico, S.W., Chemical Lecturer.
- Pagès, Albert, 34, Boulevard Henri IV., Paris, Technical Chemist.
- Paine, Augustus G., 60, Times Building, New York, U.S.A., President of Paper Making Co.
- Paine, S., 7, Exchange Street, Manchester, Pharmaceutical Chemist.
- Palmer, T. Chalkley, Box 19, Chester, Pa., U.S.A., Manufacturing Chemist.
- Palmer, Thos. C., 98, Commercial Road East, London, E., Engineer.
- Park, J., Millburn Chemical Works, Garngad Hill, Glasgow, Chemical Manager.
- Parker, Chas. E., Vine House, Peuketh, Warrington, Tanner.
- Parker, Chas. E., c/o Seabury and Johnson, East Orange, N.J., U.S.A., Chemist.
- Parker, Dr. J. Gordon, Herold's Institute, Drummond Road, Bermondsey, S.E., Head of Tanning School.
- Parker, Edw., Laburnum House, Rushford Park, Levenshulme, Manchester, Analytical Chemist.
- Parker, Thos., Manor House, Tettenhall, Wolverhampton, Electrical Engineer.
- Parker, Thos. J., Bayonne, N.J., U.S.A., Chemical Works Manager.
- Parkes, Harry, 25, Halkyn Avenue, Sefton Park, Liverpool, Copper Works Manager.
- Parr, Saml. W., Chemical Laboratory, University of Illinois, Urbana, Ill., U.S.A., Professor of Applied Chemistry.
- Parry, John, Technical Laboratory, Newport, Mon., Analytical Chemist.
- Pass, A. C., The Holmes, Stoke Bishop, Bristol, Lead Smelter.
- Passmore, Dr. F. W., 29, Wollington Road, West Norwood, Analytical and Consulting Chemist.
- Paterson, Dr. Jas. H. R., 10, Millerfield Place, Edinburgh, Paterson, John, Belle Isle Place, Workington, Cumberland, Mechanical Engineer.
- Paton, J. M. C., Messrs. Manlove, Alliott, Fryer & Co., Nottingham, Mechanical Engineer.
- Paton, W. Grant, Greenbank Alkali Works, St. Helens, Lancashire, Alkali Works Manager.
- Patterson, G., c/o The Manbré Saccharine Co., Ltd., Hammersmith, W., Technical Chemist.
- Patterson, Harry J., College Park, Prince George's Co., Md., U.S.A., Agricultural Chemist.
- Patterson, T. L., Messrs. J. Walker & Co., Sugar Refinery, Greenock, N.B., Sugar Works Manager.
- Pattinson, Dr. H. Salvin, 75 Side, Newcastle-on-Tyne, Analytical Chemist.
- Pattinson, J., 75, The Side, Newcastle-on-Tyne, Consulting Chemist.
- Pattison, J., 83, North Oswald Street, Glasgow, N.B., Chemical Merchant.
- Pattison, Percy J., 11, Park Road, West Ham, E., Colour Chemist.
- Paul, Dr. Benjamin H., 20, Victoria Street, Westminster, S.W.; and (Journals) Parkside, Kingston Vale, Putney, S.W., Consulting and Analytical Chemist.
- Paul, Jas. H., 123, Palace Road, Tulse Hill, S.W., Analytical Chemist.
- Pauli, Dr., Höchst a. Main, Germany, Chemical Manufacturer.
- Payne, J. B., 15, Mosley Street, Newcastle-on-Tyne, Manufacturing Chemist.
- Peacock, Saml., Finley's Post Office, N.J., U.S.A., Technologist.
- Peak, C. P., Bridgewater Chemical Works, Wigan, Manufacturing Chemist.
- Pearce, Jas. Stanley, Clements, Snaresbrook, Essex, Chemical Manufacturer.
- Pearce, W., Bow Common, London, E.; and (Journals) The Elms, Salway Hill, Woodford, Essex, Chemical Manufacturer.
- Pears, Andrew, jun., Spring Grove, Isleworth, Analytical Chemist.
- Pearson, Frank P., Arnold Printworks, North Adams, Mass., U.S.A., Printworks Manager.
- Pearson, Wm. H., 6, Fenchurch Buildings, London, E.C., Analytical Chemist.
- Peckiney, A. R., Salindres (Gard), France, Alkali Manufacturer.
- Peden, Jno., 58, Esplanade, Greenock, N.B., Analytical Chemist.
- Pedler, Prof. A., F.R.S., Presidency College, Calcutta, India, Professor of Chemistry.
- Pedler, J. R., 47, Tregunter Road, South Kensington, S.W., Clerk.
- Pemberton, Henry, jun., 1947, Locust Street, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
- Pemberton, Thos., South Brook Street, Leeds, Oil Manufacturer.
- Peniston, Alex. H., Lyndhurst, Theydon Bois, Essex, Pharmaceutical Chemist.
- Pennock, J. D., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Technical Chemist.
- Pentecost, S. J., Nottingham Road, New Basford, Nottingham, Lace Dresser.
- Pentermann, H. T., 37, Clifton Crescent, Peckham, S.E., Brewing Chemist.
- Peploe, D. H. T., Fairfield, Biggleswade.
- Perkin, A. G., 8, Montpelier Terrace, Hyde Park, Leeds, Technical Chemist.
- Perkin, Dr. W. H., F.R.S., The Chestnuts, Sudbury, Harrow, Research Chemist.
- Perkin, Dr. W. H., jun., F.R.S., Fairview, Wilbraham Road, Fallowfield, Manchester, Professor of Chemistry.
- Perkins, T. S., 39, Garden Place, Brooklyn, N.Y., U.S.A., Chemist (Tartar Co.).
- Perry, D., Forth and Clyde Chemical Works, Kirkintilloch, N.B., Manufacturing Chemist.
- Perry, Jos. H., 176, Highland Street, Worcester, Mass., U.S.A., Teacher of Chemistry.
- Pethybridge, Walter, 3b, Clarendon Road, Clapham Rise, S.W., Chemist and Assayer.

- Pettigrew, J., 6, St. Helen's Place, Bishopsgate, London, E.C., Technical Chemist.
- Pettigrew, Robt., c/o Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Electro-chemist.
- Petty, A., Silvertown, London, E.; and (Journals) 33, Clapton Common, E., Oil Refiner.
- Peyton, E. P., Chemical Works, Lister Street, Birmingham, Chemical Manufacturer.
- Philip, Arnold, Heriot Watt College, Edinburgh, Electro-Metallurgist and Electrical Engineer.
- Phillips, A. G., 18, Fopstone Road, South Kensington, S.W., Barrister-at-law.
- Phillips, George Brinton, 622, Race Street, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
- Phillips, H., 183, Moss Lane East, Manchester, Analytical Chemist.
- Phillips, S. Chas., 130, Fleet Street, London, E.C., Chemical Engineer.
- Phillips, Thos., Birthright View, Cornholme, Todmorden, Wood Distiller.
- Phipson, Dr. T. L., 83, Erpingham Road, Putney Common, S.W., Analytical and Consulting Chemist.
- Pieard, Hugh F. K., 18, Sandwell Mansions, West End Lane, N.W., Metallurgist.
- Pick, Dr. S., Direction der Soda Fabrik, Szezakowa, Galizien, Austria, Chemical Engineer and Manager.
- Pickard, Wm., Stafford Villa, Norfolk Park, Sheffield, Manufacturing Chemist.
- Pickles, H., Prussiate Works, Droylsden, Manchester, Technical Chemist.
- Pielsticker, Carl M., 43, Connaught Road, Harlesden, N.W., Chemical Engineer.
- Pilkington, G., Analytical Chemist.
- Pilley, Thos. W., 33, Grove Hill Road, Denmark Hill, S.E., Analytical Chemist.
- Pilling, John E., 28, Agnew Villas, Whitegate Lane, Blackpool, Chemist.
- Pipe, Jas., Messrs. Wm. Henderson & Co., Irvine, N.B., Chemical Manufacturer.
- Pitblado, L., c/o Mysore G. M. Co., Marikuppam, Mysore, India, Metallurgical Chemist.
- Pitt, T., 16, Coleman Street, London, E.C., Manufacturing Chemist.
- Pittuck, F. W., 19, Stratford Grove, Newcastle-on-Tyne, Technical Chemist.
- Platten, Frank, c/o Elliot's Metal Co., Limited, Selly Oak, near Birmingham, Metallurgical Chemist.
- Platts, Jno. C., Ryecroft Glen, Dore Station, Sheffield, Metallurgical Chemist.
- Playfair, David J., 12, Woodside Terrace, Glasgow, Manufacturing Chemist.
- Pocklington, Hy., 41, Virginia Road, Leeds, Assurance Co.'s Local Manager.
- Pollitt, R. B., 12, Mark Lane, London, E.C., Civil Engineer.
- Pollock, A., Dillchip Turkey-red Dyeworks, Bonhill, Dumbartonshire, Dyeworks Manager.
- Pomeroy, Dr. Chas. T., 190, Mount Pleasant Avenue, Newark, N.J., U.S.A., Ink Manufacturer.
- Pond, J. A., 99, Queen Street, Auckland, New Zealand, Analytical Chemist.
- Pont, Pierre S. du, Wilmington, Del., U.S.A., Explosives Manufacturer.
- Poole, Thos., 25, Water Street, Liverpool, Chemical Broker.
- Pooley, T. A., 76, Grove Lane, Denmark Hill, S.E., Analytical Chemist.
- Pope, Frank, Estes Park, Colorado, U.S.A., Chemist.
- Pope, S., Camden Works, Runcorn, Chemical Works Manager.
- Pott, W. Hamilton, 68, Sumner Street, Southwark Bridge Road, London, S.E., Vinegar Brewer.
- Potter, Chas. E., Love Lane Sugar Refinery, Liverpool, Sugar Works Chemist.
- Potter, Chas. J., Heaton Hall, Newcastle-on-Tyne, Cement Manufacturer.
- Potter, E. P., Hollinhurst, Bolton-le-Moors, Alkali Manufacturer.
- Potts, Joseph T., Price's Patent Candle Co., Bromboro' Pool, near Birkenhead, Chemist.
- Powell, A. Ernest, 59, Egerton Road, Fallowfield, Manchester, Oil Merchant.
- Powell, L. S., 5, Campden Hill Square, London, W., Electrician.
- Pratt, Walter E., Chemical Laboratory, Midland Railway Co., Derby, Analytical Chemist.
- Prentice, Manning, Stowmarket, Suffolk, Chemical Manufacturer.
- Prescott, Dr. Albert B., Ann Arbor, Mich., U.S.A.
- Preston, Alf., 4, Market Street, Bury, Lancashire, Chemist.
- Preston, E. S., Park House Cottage, Park Road, Swanage, Civil Engineer.
- Preston, R., Hill End, Holcombe, near Manchester, Manufacturing Chemist.
- Price, A. F., 524, Sacramento Street, San Francisco, Cal., U.S.A., Analytical Chemist.
- Price, Raymond B., c/o Boston Woven Hose and Rubber Co., Cambridgeport, Mass., U.S.A., Chemical Engineer.
- Price, T. Spiers, 15, Seething Lane, London, E.C., Secretary.
- Prinz, Dr. Otto, Sesto Fiorentino, Italy, Editor.
- Pritchard, Edgar J., Burrows, Swansea, Works Manager.
- Pritchard, W. S., Farnworth, Widnes, Chemical Works Manager.
- Procter, C., Government Laboratory, Somerset House, London, W.C., and (Journals) 359, Upland Road, Dulwich, S.E., Analytical Chemist.
- Procter, H. R., Yorkshire College, Leeds; and (Journals) Thornleigh, Wheatley Road, Hkley, Yorks, Lecturer on Tanning.
- Procter, J. W., Skeldergate Bridge, York, Manure Manufacturer.
- Proctor, Miss Anne J., Free Library, Widnes, Librarian.
- Proctor, W. W., 33, The Side, Newcastle-on-Tyne, Assayer and Analytical Chemist.
- Proude, Jas., 13, Oak Terrace, Halifax, Yorks, Soap Works Chemist and Manager.
- Pullar, Herbert S., Rosebank, Perth, N.B., Dyer.
- Pullar, Sir Robert, Pullar's Dyeworks, Perth, N.B., Dyer.
- Pullar, R. D., Pullar's Dyeworks, Perth, N.B., Dyer.
- Pullman, John, 95, Ashley Gardens, Victoria Street, London, S.W., Leather Dresser.
- Pureell, M. F., 13, Victoria Street, Westminster, S.W., Consulting Chemical Engineer.
- Purdie, Dr. Thos., F.R.S., 14, South Street, St. Andrews, N.B., Professor of Chemistry.
- Pütz, Mrs. Helen, 16-17, Great St. Helens, London, E.C., Chemical Merchant.

Q

- Quibell, Oliver, Magus Lodge, Newark-on-Trent, Manure Manufacturer.
- Quinke, Dr. F., Chemische Fabrik Rhenania, Stolbergh bei Aachen, Germany, Analytical Chemist.
- Quinn, J. Cardwell, Manor Rubber Mills, Aston Cross, Birmingham, Chemist and Manager.

- Richards, E., 1621 H. Street, Washington, D.C., U.S.A., Analytical Chemist.
- Richards, W. A., Sandbach, Cheshire, Alkali Works Manager.
- Richardson, Clifford, Laboratory, Barber Asphalt Paving Co., Long Island City, N.Y., U.S.A., Chemical Engineer and Consulting Chemist.
- Richardson, C. T., Monkton Lodge, Jarrow-on-Tyne, Alkali Manufacturer.
- Richardson, D. B., Hartfield, Cove, Dumbartonshire, N.B., Chemical Merchant.
- Richardson, Col. J. G. F., Elmfield, Stonegate, Leicester, Analytical Chemist.
- Richardson, F. W., 2, Farecliffe Place, Bradford, Yorkshire, Analytical Chemist.
- Richardson, G. E., Howley Park, Batley, Yorks, Manufacturing Chemist.
- Richardson, Jas. C., 19, Claremont Square, London, N., Electrochemical Engineer.
- Richardson, S. M., 415, Main Street, Bonhill, N.B., Analytical Chemist.
- Richardson, Walter W., 1, Montpellier Terrace, Cliff Road, Leeds, Manufacturing Chemist.
- Richardson, Wm. H., Newsky Thread Mills, Malaja Bolotnaja, St. Petersburg, Russia, Textile Chemist.
- Richmond, H. D., 7, Cambrian Road, Richmond, Surrey, Chief Chemist (Aylesbury Dairy Co.).
- Richmond, W. H., Liver Alkali Co., Limited, Ditton Road, Widnes, Alkali Manufacturer.
- Riddell, R., 87, Horninglow Street, Burton-on-Trent, Brewer.
- Ridding, Howard C., A.R.S.M., 20, Algernon Road, Birmingham, Analytical Chemist.
- Rideal, Dr. Samuel, Chemical Laboratory, 28, Victoria Street, Westminster, S.W., Analytical and Consulting Chemist.
- Ridsdale, C. H., Hutton Grange, Guisboro', Yorks, Analytical Chemist.
- Rigby, John S., 35, Bagot Street, Wavertree, Liverpool, Chemical Manufacturer.
- Riker, Jno. J., 45, Cedar Street, New York City, U.S.A., Merchant.
- Riley, E., 2, City Road, Finsbury Square, London, E.C., Metallurgical Chemist.
- Riley, Jas., 168, St. Vincent Street, Glasgow, Steel Manufacturer.
- Riley, J. E., Arden Hall, near Acerrington, Chemical Manufacturer.
- Riley, J., Hapton Chemical Works, Acerrington, Chemical Manufacturer.
- Riley, James, Chemical Works, Oakenshaw, near Acerrington, Lancashire, Technical Chemist.
- Riley, Jno., Thornliebank, near Glasgow, Print Works Manager.
- Riley, Wm., Castleton, Manchester, Chemical Manufacturer.
- Rintoul, Wm., Royal Gunpowder Factory, Waltham Abbey, Essex, Explosives Chemist.
- Ripley, H., Bowling Dyeworks, Bradford, Yorkshire, Dyer.
- Ritchie, Robt., Shawfield Works, Rutherglen, near Glasgow, Technical Chemist.
- Ritson, T. N., Gas Works, Kendal, Gas Engineer.

Rix, W. P., Doulton & Co., Lambeth Art Pottery, London, S.E., Pottery Manager.

Robbins, J., 147, Oxford Street, London, W., Pharmaceutical Chemist.

Roberts, C. F., Linfitts, Delph, via Oldham, Chemical Merchant.

Roberts, Ernest H., Hollydale, Allfarthing Lane, Waudsworth, S.W., Analytical Chemist.

Roberts, F. A., Cornbrook Chemical Works, Manchester, Chemical Manufacturer.

Roberts, F. G. Adair, Lion House, Amburst Park, Stamford Hill, N., Chemical Manufacturer.

Roberts, J. H. M., 14, St. James' Road, Brixton, S.W., Brewer.

Roberts, R. Wightwick, 22, Calle Arturo Prat, Valparaiso, Chili, Analytical and Consulting Chemist.

Robertshaw, C. Dawson, e/o Dr. Lewkowitsch, Lancaster Avenue, Fennell Street, Manchester, Chemist.

Robertson, Alex., Argyle Chemical Works, Oban, N.B., Manufacturing Chemist.

Robertson, Alex. A., South Edgehill House, Langside, Glasgow, Oil Works Chemist.

Robertson, Geo. H., 30, Hemstead Road, West Hampstead, N.W., Electro Chemist.

Robertson, Robt., Royal Gunpowder Factory, Waltham Abbey, E., Analytical Chemist.

Robertson, R. A., 8, Park Street East, Glasgow, Mechanical Engineer.

Robins, Walter, 9, Northbrook Lead, Lee, S.E., Chemist.

Robinson, G. C., Royal Institution, Hull; and Laboratory, Bond Street, Hull (for Journals), Chemical Lecturer.

Robinson, H. H., Imperial College, Hankow, China, Professor of Chemistry.

Robinson, Jos., Farnworth, Widnes, Chemical Manufacturer.

Robinson, Jno., 9, Stanley Villas, Greenway Road, Runcorn, Chemical Engineer.

Robinson, Thomas, 401, West Street, Glasgow, Chemical Works Manager.

Robinson, Wm. S., 1112 Dodge Street, Omaha, Neb., U.S.A., Chemist and Assayer.

Robson, Jas., 204, George Street, Glasgow, Chemist.

Rodda, Edw. D., 6, Gold Street, Roath, Cardiff, Engineer.

Rodger, Edw., 1, Clairmont Gardens, Glasgow, W.

Rogers, Harry, 5, Stoke Newington Common, London, N., Secretary (Victoria Stone Co.).

Rogers, Capt. Jno. Martin, Mount Hawke, Scorrier, Cornwall, Mining Engineer.

Rogerson, W. J., 38, Southwark Street, London, S.E., Wholesale Druggist.

Rollin, J. C., 1, St. Nicholas Buildings, Newcastle-on-Tyne, Secretary.

Roscoe, Sir Henry, F.R.S., 10, Bramham Gardens, South Kensington, S.W., Consulting Chemist.

Roscow, Jno. F., 33, Kossneth Street, Pawtucket, R.I., U.S.A., Print Works Chemist.

Rose, Andrew A., 172, Leith Walk, Edinburgh, Merchant.

Rose, Hugh, 172, Leith Walk, Edinburgh, Paint and Varnish Manufacturer.

Rosell, Dr. Claude A. O., 100, East 17th Street, New York, U.S.A., Chemist.

Rosenheim, Dr. Otto, 68, Belsize Park Gardens, Hampstead, N.W., Analytical and Research Chemist.

Ross, Alex. J. J., Tayavalla, Falkirk, N.B., Chemical Manufacturer.

Ross, Arthur, 1, Glengall Road, Old Kent Road, London, S.E., Analytical Chemist.

Ross, J. G., 28, Gainsboro' Road, Wavertree, Liverpool, Analytical Chemist.

Rothwell, C. F. Seymour, 88, George Street, Moss Side, Manchester, Print Works Chemist.

Rottenburg, Paul, e/o Messrs. Leisler, Boek & Co., 130, Hope Street, Glasgow, N.B., Chemical Merchant.

Rouillard, R. A., 2, Springfield Road, Wimbledon, Analytical Chemist.

Round, Wm., 10, Northampton Street, Birmingham, Analytical Chemist.

Rowe, G. Vanner, 11, The Green, Stratford, E., Chemist.

Rowell, W. A., 21, Victoria Square, Newcastle-on-Tyne, Manufacturing Chemist.

Rowland, W. L., 4800, Chester Avenue, Philadelphia, Pa., U.S.A., Chemist.

Rowlands, Wm. Ellison, 34, Tynwald Hill, Stoneycroft, Liverpool, Paint Manufacturer.

Rowntree, B. Seeborn, The Cocoa Works, York, Cocoa Manufacturer.

Roxburgh, J. W., Levenbank Works, Jamestown, Dumbartonshire, N.B., Print Works Manager.

Royle, T., Dalton House, Upton Lane, Forest Gate, E., Chemical Engineer.

Royse, S. W., St. Andrew's Chambers, Albert Square, Manchester, Chemical Engineer.

Royston, Ernest R., 15, Water Street, Liverpool, Patent Agent.

Rudge, Alfred, Sutton Alkali Works, St. Helens, Analytical Chemist.

Rudolf, Norman S., Sewan, Sarun, Bengal, India, Analytical and Consulting Chemist.

Ruffle, Jno., Groll Brook, Neuth, Glamorganshire, Mannre Works Chemist.

Rumble, C., Belmont Works, Battersea, London, S.W., Candle Works Chemist.

Rump, Ernst, The Leeds Phosphate Works, Haunslet, Leeds, Manager.

Russell, D., Cadham, Markinch, Fife, N.B., Paper Maker.

Russell, Jno., Anchor Brewery, Britten Street, Chelsea, London, S.W., Brewer.

Russell, O. F., Laboratory, 7, Old Swan Lane, London, E.C., Brewer's Chemist.

Russell, Dr. W. J., F.R.S., St. Bartholomew's Hospital, London, E.C., Professor of Chemistry.

Russell, Wm., Summerlee Ironworks, Coatbridge, N.B., Analytical Chemist.

Rutter, Chas. H., Gas Works, Hove, Sussex, Civil Engineer.

Ryder, C. E., e/o Messrs. Elkington, Newhall Street, Birmingham, Electro Metallurgist.

Ryland, Howard P., Moxhall Park, Erdington, Birmingham, Agricultural Chemist.

S

Saalfeld, Adolphe, 38-40, Lancaster Avenue, Fennell Street, Manchester, Chemical Merchant.

Saarbach, Dr. L., 23, William Street, New York, U.S.A., Consulting Chemist.

Sach, Robt., e/o Señor César Gareia, Honda, Rep. of Columbia, South America, Assayer.

Sadler, A. E., Sand Hall, Ulverston, Lancashire, Manufacturing Chemist.

Sadler, S. A., Middlesbrough-on-Tees, Colour Manufacturer.

Sadtler, Dr. S. P., 145, North 10th Street, Philadelphia, Pa., U.S.A., Consulting Chemist.

Sadtler, Dr. Saml. S., 204, North 34th Street, Philadelphia, Pa., U.S.A., Chemist (U.S. Customs).

Saint, W. Johnston, 11, Queen's Road, Aberdeen; and (Journals) Kurfuerstenstrasse 5, Bonn-Poppelsdorf, Germany, Analytical Chemist.

Salamon, A. G., 1, Fenchurch Avenue, London, E.C., Consulting Chemist.

Salamon, Jno., Rainham, S.O., Essex, Manufacturing Chemist.

Salis-Mayenfeld, Dr. E. von., e/o Hohenhausen & Co., Ltd., Blackley, near Manchester, Technical Chemist.

Salmon, E. H. R., Brazilian Extract of Meat Factory, Cachoeira, Rio Grande do Sul, S. Brazil, Analytical Chemist.

Salt, Arthur P., Sunnyside, Pinner Road, Harrow, Analytical Chemist.

Salter, Chas. T. C., 84, St. Paul's Road, Camden Square, N.W., Scientific Journalist.

Saltnarsh, J. G., West Mount, Upton, Macclesfield, Works Chemist.

Samuel, W. Cobden, 337, Norwood Road, West Norwood, S.E., Analytical Chemist.

Samuelson, Rt. Hon. Sir Bernard, Bart., F.R.S., 56 Prince's Gate, London, S.W., Ironmaster

- Samuelson, Godfrey B., c/o Messrs. W. T. Glover & Co., Salford, Electrical Manufacturer.
- Sanderson, John, P.O. Box 84, Middlesbrough, Kentucky, U.S.A., Chemist.
- Sandon, R., 42, Lewisham Road, Dartmouth Park, N.W., Examiner at Patent Office.
- Sandys, Hon. Michael, Pyrford Place, Ripley, Surrey, Stockbroker.
- Sanford, P. Gerald, Analytical Laboratory, 20, Cullum Street E.C., Analytical and Consulting Chemist.
- Saniter, E. H., 11, New Market Street, Wigan, Analytical Chemist.
- Sankey, Chas. H., Iron Bridge and Essex Wharves, Canning Town, E., Fire- and Acid-Proof Goods Maker.
- Santer, Herbert, Albion Brewery, Caledonian Road, N., Brewer.
- Savage, Arthur E., c/o Proprietary Co., Broken Hill, New South Wales, Metallurgist.
- Savage, W. W., 109, St. James's Street, Brighton, Pharmaceutical Chemist.
- Sawers, Wm. D., Balaghat Mysore Mines, Oorgaum, Mysore State, South India, Chemist.
- Sawyer, Harris E., 37, Gates Street, South Boston, Mass., U.S.A., Chemist.
- Sayer, Harry, 60, Lancaster Road, Carnforth, Lancashire, Chemist.
- Sayers, Jos. J., Mayville, Stevenston, Ayrshire, Explosives Chemist.
- Seales, F. Shillington, Wearmouth Paper Mill, Sunderland, Paper Maker.
- Schaack-Sommer, Dr. G., 323, Vauxhall Road, Liverpool, Sugar Refiner.
- Schad, Julius, York Buildings, 33, Mosley Street, Manchester, Aniline Co.'s Agent.
- Schad, Dr. Philip, 4, Dyar Terrace, Winnington, Northwich, Analytical Chemist.
- Schäppi, Dr. H., Miltödi, Canton Glarus, Switzerland, Analytical Chemist.
- Scheel, Wm. H., 78, Pine Street, New York City, U.S.A., Manufacturing Chemist.
- Schellhaas, H., 38, Navigation Road, Northwich, Mechanical Engineer.
- Scheurer-Kestner, Dr. A., 8, Rue Pierre-Charron, Paris, France, Chemical Manufacturer.
- Schidrowitz, Dr. P., 102, Oxford Gardens, Notting Hill, W., Research Chemist.
- Schieffelin, Dr. W. Jay, 841, Southern Boulevard, New York, U.S.A., Manufacturing Chemist.
- Schiller, Louis J., The American Sugar Refining Co., Granite Street, South Boston, Mass., U.S.A., Chemist.
- Schleicher, Francis J., 38, West Tenth Street, Long Island City, N.Y., U.S.A., Printing Ink and Varnish Chemist.
- Schlesinger, Dr. Jas., P.O. Box 368 Pretoria, S.A.R., Analytical Chemist.
- Schlichter, Dr. H., Thothmes House, Gisburn Road, Hornsey, N., Textile Chemist.
- Scholefield, H. E., Greenwood, Victoria Park, Wavertree, Liverpool, Chemical Manufacturer.
- Schönzeder, John, 22, Petit Moskaya, St. Petersburg, Russia, Metallurgical Chemist.
- Schriever, John, Greenpoint Chemical Works, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
- Schroeder, E. August, c/o Church and Co., 36, Ash Street, Brooklyn, N.Y., U.S.A., Chemist.
- Schryver, Dr. S. B., University College, Liverpool, Assistant Lecturer on Chemistry.
- Schulze, Dr. Karl E., Chemische Fabrik Lindenhof, Waldhof bei Mannheim, Germany, Technical Chemist.
- Schunck, Dr. E., F.R.S., Kersal, near Manchester, Colour Chemist.
- Schüpphaus, Dr. Robt. C., 118, Pennsylvania Avenue, Brooklyn, N.Y., U.S.A., Consulting Chemist.
- Schwab, Dr. L. C., Sedanstrasse 53, Bernburg, Anhalt, Technical Chemist.
- Schweich, Emil, 110, Fenchurch Street, London, E.C., Technical Chemist.
- Schweitzer, Dr. H., 159, Front Street, New York City, U.S.A., Analytical Chemist.
- Scott, Andrew, 2, Teviot Terrace, Kelvinside, Glasgow, Analytical Chemist.
- Scott, Andrew R., Carnlyle Chemical Works, Parkhead, Glasgow, Manufacturing Chemist.
- Scott, Ernest G., 67, Lord Street, Liverpool, Soap Works Chemist.
- Scott, F., Messrs. Fred. Scott & Co., Littleboro', near Manchester, Calico Printer.
- Scott, F. Walter, 44, Christian Street, London, E., Engineer.
- Scott, Herbert, c/o Gerspacher and Co., Usina Wigg Miguel Burnier, Minas, Brazil, Metallurgist.
- Scott, Jno. Gillespie, Annislea, Northfield, Liberton, near Edinburgh, Analytical Chemist.
- Scott-Smith, G. E., 67, Surrey Street, Sheffield, Analytical Chemist.
- Scott, Wm., 168, Eglinton Road, Plumstead, S.E., Sugar Chemist.
- Seovell, M. A., Lexington, Kentucky, U.S.A., Agricultural Chemist.
- Scrutton, W. J. (or Willis) (1/o California), 18, Billiter Street, London, E.C., Analytical Chemist.
- Serymgeour, A., c/o African Gold Recovery Co., Box 1283, Johannesburg, S.A.R., Assayer.
- Serymgeour, Wm., Afrikander Gold Mining Co., Box 38, Klerksloep, S.A.R., Chemist.
- Sendder, F., Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Analytical Chemist.
- Seabrooke, H. Cecil, The Echoes, Grays, Essex, Chemical Research Assistant.
- Seamon, W. H., Socorro, New Mexico, U.S.A., Director of School of Mines.
- Searl, Albert, Phoenix Mills, Dartford, Kent, Manager (Barringtons, Wellcome, and Co.).
- Sefton-Jones, Herbert, c/o W. P. Thompson and Co., 31, High Holborn, W.C., Analytical Chemist.
- Segner, P., 26, Princess Street, Manchester, Chemical Agent.
- Segundo, E. C. de, 28, Victoria Street, Westminster, S.W., Chemical Engineer.
- Seldner, Rudolph, 217, Jefferson Avenue, Brooklyn, New York, U.S.A., Instructor in Chemistry.
- Semet, Louis, 217, Chaussée de Vleurgat, Brussels, Alkali Manufacturer.
- Senger, Robt., 174, Pearl Street, New York City, U.S.A., Manufacturing Chemist.
- Settle, Wm., Connaught House, Haulgh, Bolton, Mining Engineer.
- Sevin, C., c/o Dollman & Pritchard, 39, King Street, Cheap-side, E.C., Chemical Engineer and Oil Refiner.
- Sewell, Parker, 100, Marlborough Street, South Shields, Analytical Chemist.
- Sexton, Prof. A. Humboldt, 204, George Street, Glasgow, Professor of Chemistry.
- Seymour, J. R. W., Northeroft Farm, Inkpen, near Hungerford, Berks.
- Seymour-Jones, A., Cambrian Leather Works, Wrexham, Leather Manufacturer.
- Shadwell, J. E. L., Meadowbank, Melksham, Wilts, Analytical Chemist.
- Shallcross, Arthur, Excelsior Chemical Works, Corbett Street, Bradford, near Manchester, Chemical Manufacturer.
- Shallcross, T. H., Corbett Street, Bradford, near Manchester, Manufacturing Chemist.
- Shanks, Arch., Bridgend Mills, Dalry, Ayrshire, N.B., Chemist.
- Shapleigh, W., Welsbach Incandescent Gas Light Co., Gloucester City, N.J., U.S.A., Technical Chemist.
- Shapley, Fred., c/o W. P. Fuller and Co., 21, Front Street, San Francisco, Cal., U.S.A., Paint and Colour Chemist.
- Sharp, Henry, 11, Delahay Street, Westminster, S.W., Civil Engineer.
- Sharp, James, The Towers, Low Moor, near Bradford, Yorks, Dyer.
- Sharpe, Granville H., 11 & 12, Great Tower Street, London, E.C., Analytical Chemist.
- Sharples, Stephen P., 13, Broad Street, Boston, Mass., U.S.A., Analytical Chemist.

- Sharpley, Wm. P., Ditton Copper Works, Widnes, Lancashire, Analytical Chemist.
- Shaw, F. W., 99, Heapey Road, Chorley, Lancashire, Bleach Works Chemist.
- Shaw, Geo., 35, Temple Row, Birmingham, Patent Agent.
- Shaw, H. Dixon, Bond Street, Dewsbury, Yorks, Analytical Chemist.
- Shaw, Saville, Durham College of Science, Newcastle-on-Tyne, Chemical Demonstrator.
- Shearer, A., 36, Demesne Road, Alexandra Park, Manchester, Technical Chemist.
- Sheffield, Oscar E., 57, Ferntower Road, Canonbury, N., Chemical Student.
- Sheman, G. W., c/o Boston Woven Hose and Rubber Co., Cambridgeport, Mass., U.S.A., Chemical Engineer.
- Shenstone, W. A., Clifton College, Bristol, Chemical Lecturer.
- Shenton, Jas. P., 34, Lansdowne Road, Albert Park, Didsbury, Manchester, Analytical Chemist.
- Shepard, Dr. Chas. U., 68, Meeting Street, Charleston, S.C., U.S.A.
- Shepherd, H. H. B., Anglo-Continental Guano Works, Tidal Basin, Victoria Docks, E., Chemist.
- Shepherd, Jas., Rossead Castle, Burntisland, N.B., Floor-cloth Manufacturer.
- Sheppce, Lt.-Col. F. F., Birtley House, Chester-le-Street, Co. Durham, Colliery Proprietor.
- Sherman, G. W., c/o Boston Woven Hose and Rubber Co., Cambridgeport, Mass., U.S.A., Chemical Engineer.
- Shidzuki, Iwaichiro, c/o Nippon Chemical Manufacturing Co., Onoda, Yamaguchi-ken, Japan, Chemist.
- Shield, H., c/o Messrs. Fawcett, Preston, & Co., Ltd., 17, York Street, Liverpool, Civil Engineer.
- Shields, Dr. J., University College, London, W.C., Chemist.
- Shimidzu, Tetsukichi, 6641, Woodlawn Avenue, Chicago, Ill., U.S.A., Analytical Chemist.
- Shimose, Masachika, Kaigun Zobeisho, Tokyo, Japan, Chemical Engineer.
- Shishkoff, Sergius A., Elabonga, Govt. of Viatka, Russia, Glassworks Manager.
- Shishkoff, Waldemar A., Tchäsovnia, Simbirsk, Russia, Chemical Engineer.
- Shutt, Frank T., Central Experimental Farm, Ottawa, Canada, Agricultural Chemist.
- Siebold, L., Broomville Avenue, Sale, Manchester, Analytical Chemist.
- Sill, T. T., c/o United Alkali Co., Ltd., Weston Works, near Runcorn, Alkali Works Manager.
- Sillar, W. Cameron, The Native Guano Co., Limited, 29, New Bridge Street, Blackfriars, E.C., Director (Native Guano Co.).
- Silvester, Harry, Holyhead Road, Handsworth, Birmingham, Analytical and Consulting Chemist.
- Simomura, T. K., c/o C. and J. Favre-Brant, Kawaguchi, Osaka, Japan, Technical Chemist.
- Simon, H., 20, Mount Street, Manchester, Civil Engineer.
- Simonds, Dr. F. M., 20, Platt Street, New York, U.S.A., Mining Engineer and Assayer.
- Simpson, Chas. H., Moor Top House, Ackworth, Pontefract, Soap Manufacturer.
- Simpson, W. S., 95, Darenth Road, Stamford Hill, N., Analytical Chemist.
- Sims, T. H., Mayfield Printworks, Manchester, Printworks Chemist.
- Sinclair, Dr. Wm., Young's Oil Co., Lim., Uphall, N.B., Chemist.
- Sindall, R. W., "Daily Chronicle" Paper Mills, Sittingbourne, Kent, Paper Mills Chemist.
- Singer, Ignatius, The Poplars, Capel Street, Calverley, Yorks, Manufacturing Chemist.
- Sisson, G., jun., c/o Washington Chemical Co., Lim., Washington Station, R.S.O., Co. Durham, Works Manager.
- Skaife, Wilfred T., 630, Sherbrooke Street, Montreal, Canada, Sugar Chemist.
- Skelton, John R., Thorpe St. Andrew, Norwich, Technical Chemist.
- Skilton, C. F. E., c/o Messrs. Ind, Coope, & Co., Burton-on-Trent, Brewer.
- Skinner, C. Weeding, Wansfell, Theydon Bois, Essex, Manufacturing Chemist.
- Skurray, Thos., United Breweries, Abingdon, Berks, Brewer.
- Slade, H. E., Streatham Common, London, S.W., Rubber Works Manager.
- Slater, H. H., Laboratory and Testing Office, Grays, Essex, Portland Cement Expert.
- Slater, Sydney H., Post Restante, Johannesburg, S.A.R.
- Slatter, Geo. W., Saltaire Works, Shipley, Yorkshire, Analytical Chemist.
- Sloeam, Frank L., Linden Avenue, E.E., Pittsburgh, Pa., U.S.A., Chemist.
- Smail, J. L., Blackmount, Chislehurst, Kent, Chemical Manufacturer.
- Smetham, A., 18, Brunswick Street, Liverpool, Analytical Chemist.
- Smiles, Jas., Blandfield Chemical Works, Canonmills, Edinburgh, Manufacturing Chemist.
- Smith, Alfred, Excelesior Chemical Works, Clayton, Manchester, Manufacturing Chemist.
- Smith, Bernard E., 45, Percy Park, Tynemouth, Alkali Works Inspector.
- Smith, E. Ellsworth, 262, Fifth Avenue, New York, U.S.A., Consulting Physiological Chemist.
- Smith, Edgar B., c/o Messrs. Bart, Boulton, and Haywood, Selzaete, Belgium, Chemist.
- Smith, Edgar F., 35, Amptill Square, Hampstead Road, London, N.W., Analytical Chemist.
- Smith, Ernest A., Metallurgical Laboratory, Royal College of Science, South Kensington, S.W., Assistant Instructor in Assaying.
- Smith, Francis P., c/o Harrison Bros. and Co., 35th Street and Grays Ferry Road, Philadelphia, Pa., U.S.A., Chemist.
- Smith, Fred., Box 1324, Johannesburg, S.A.R., Analytical Chemist.
- Smith, G., Polmont Station, Scotland, Explosives Works Manager.
- Smith, G. Henderson, Clerniston, Green Bank Road, Sefton Park, Liverpool, Chemist.
- Smith, Harry, 33, Withington Road, Whalley Range, Manchester, Technical Chemist.
- Smith, Harry E., 133, 26th Street, Milwaukee, Wis., U.S.A., Analytical Chemist.
- Smith, H. R., 1, Aubert Park, Highbury, London, N., Analytical Chemist.
- Smith, H. Wood, c/o May and Baker, Lim., Battersea, S.W., Analytical Chemist.
- Smith, Jas. Cruickshank, 32, Great Guildford Street, Southwark, S.E., Works Manager.
- Smith, Jas. F., 439, Stratford Road, Sparkhill, Birmingham, Analytical Chemist.
- Smith, J., Ash Grove House, Radcliffe, Manchester.
- Smith, Dr. J. H., Wollishofen, Zurich, Switzerland, Chemical Lecturer.
- Smith, J. Johnstone, Lockwood Brewery, Huddersfield, Brewing Chemist.
- Smith, J. Tertius, c/o Jeyes' Sanitary Compound Co., Ltd., Plaistow, Essex, Technical Chemist.
- Smith, Jno. W., Mass. Inst. of Technology, Boston, Mass., U.S.A., Analytical Chemist.
- Smith, J. Wm., Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Works Manager.
- Smith, Linton, Messrs. Smith and Painter, Wilmington, Del., U.S.A., Manufacturing Chemist.
- Smith, R. Greig, Durham College of Science, Newcastle-on-Tyne, Analytical Chemist.
- Smith, R. Watson, Young's Oil Co., Ltd., Chemical Works, Bathgate, N.B., Chemical Works Manager.
- Smith, S., 35, Amptill Square, Hampstead Road, London, N.W., Analytical Chemist.
- Smith, T. Reader, Urban District Council, Kettering, Surveyor, Assoc. M. Inst. C.E.
- Smith, Walter E., 17, Jenkins Street, Providence, R.I., U.S.A., Instructor in Chemistry.
- Smith, Watson, 34, Upper Park Road, Haverstock Hill, N.W., Editor of Society's Journal.
- Smith, Wilfred, 182, West Street, Glasgow, Chemical Manufacturer.

- Smith, W., 10, Corn Street, Bristol, Chemical Merchant.
 Smithells, Prof. A., Yorkshire College, Leeds, Professor of Chemistry.
 Smithers, E. O., Dashwood House, 9, New Broad Street, London, E.C., Chemical Agent.
 Smithson, J., Park Printworks, Halifax, Stuff Printer.
 Smithson, Saml., Ravensthorpe, near Dewsbury, Yorks, Dyer and Drysalter.
 Snape, Dr. H. Lloyd, University College, Aberystwith, Professor of Chemistry.
 Soames, J. K., Thames Soap and Candle Works, Greenwich, S.E., Soap and Candle Manufacturer.
 Sohn, Chas. E., Hop Exchange, London, S.E., Analyst.
 Solvay, Armand, 25, Rue Prince Albert, Brussels, Gérant de la Société Solvay et Cie.
 Solvay, Ernest, 43, Rue des Champs Elysées, Brussels, Alkali Manufacturer.
 Sommer, Adolf, corner 1st and Binney Streets, East Cambridge, Boston, Mass., U.S.A., Pharmaceutical Chemist.
 Sonstadt, Edw., Church Fields, Cheshunt, Herts, Chemical Technologist.
 Southern, Thos., Jr., Wheathill Chemical Works, St. Simon Street, Salford, Manufacturing Chemist.
 Soward, A. W., 28, Therapia Road, Honor Oak, S.E., Principal Clerk (Legacy Duty Office).
 Sowerby, Thos. H., Sherwell, Dartmouth Place, Blackheath, S.E., Soap Manufacturer.
 Sowerby, W. M., 12, Upper Queen's Terrace, Fleetwood, Lancashire, Alkali Works Manager.
 Sowter, Alf., 208, Bedford Hill, Balham, S.W., Assayer.
 Spackman, Chas., Roschaugh, Clitheroe, Lancashire, Portland Cement Manufacturer.
 Speakman, J. J., Stanley Villas, Greenway Road, Runcorn, Chemical Works Clerk.
 Spence, D., Alum Works, Manchester, Alum Manufacturer.
 Spence, F., Alum Works Manchester, Alum Manufacturer.
 Spence, J. Napier, Heathfield, Harrow-on-the-Hill, Teacher of Chemistry.
 Spence, J. W., 58, Dobbie's Loan, Glasgow, Drysalter.
 Spencer, Jno., Globe Tube Works, Wednesbury, Tube Manufacturer.
 Spencer, J. W., Newburn, Newcastle-on-Tyne, Steel Manufacturer.
 Spiegel, Dr. Adolf, Messel, bei Darmstadt, Germany, Analytical Chemist.
 Spies, Adolph, 102, Fenchurch Street, London, E.C., Chemical Merchant.
 Spies, Hermann, 102, Fenchurch Street, London, E.C., Chemical Merchant.
 Spiller, A., 2, St. Mary's Road, Canonbury, N., Electrician.
 Spiller, J., 2, St. Mary's Road, Canonbury, London, N., Consulting Chemist.
 Sprengel, Hermann Johann Philipp, Ph.D. (Heidelb.), F.R.S., Royal Prussian Professor (titular), Savile Club, 107, Piccadilly, London, W.
 Squire, Percy, 11, Wine Office Court, Fleet Street, London, E.C., Printing Ink Manufacturer.
 Squire, P. W., 413, Oxford Street, London, W., Pharmaceutical Chemist.
 Squire, Dr. W. S., Clarendon House, St. John's Wood Park, N.W., Chemical Engineer.
 Stacey, H. G., 300, High Holborn, London, W.C., Manufacturing Chemist.
 Stafford, Chas. H., c/o The Birkaere Printing Co., Birkaere, Chorley, Colourist.
 Stahl, Dr. K. F., 57th Street and A. V. Ry., Pittsburgh, Pa., U.S.A., Chemical Works Manager.
 Stanford, E. C. C., Glenwood, Dalmeir, N.B., Chemical Manufacturer.
 Stanger, W. Harry, Broadway Testing Works, Westminster, S.W., Engineer.
 Stanley, C. L., c/o Chas. Stanley and Son, Wath, via Rotherham, Oleic Acid Manufacturer.
 Staunings, John, Broadfield, Leyland, near Preston, Bleacher.
 Stantial, Frank G., c/o Cochrane Chemical Co., Everett, Mass., U.S.A., Technical Chemist.
 Staples, H. J., Spendon, Derby, Colour Manufacturer.
 Staples, Sir Nath. A., Bart., Lissan, Cookstown Ireland.
 Stark, J. E., 31, Highfield South, Rock Ferry, near Birkenhead, Works Manager (Price's Patent Candle Co.).
 Starling, J. H., 32, Craven Street, Strand, London, W.C., Analytical Chemist.
 Stead, J. Christopher, Mitre Works, Cordova Road, Bow, E., Chemist and Manager.
 Stead, J. E., 5, Zetland Road, Middlesbrough-on-Tees, Analytical Chemist.
 Stead, W. H., 23, Boundary Street, Liverpool; and (Journals) Orchard Place, Blackwall, E., Oil Refiner.
 Stearns, Fred. K., Detroit, Mich., U.S.A., Manufacturing Chemist.
 Stebbins, J. H., 114, Pearl Street, New York, U.S.A., Analytical Chemist.
 Steedman, H. R., Goffryn, Carrick Road, Ayr, N.B., Chemical Manufacturer.
 Steel, R. Elliott, Northampton and County School, Northampton, Headmaster.
 Steel, Thos., Colonial Sugar Refinery, Sydney, N.S.W., Sugar Chemist.
 Stenhouse, T., 8, West Street, Rochdale, Analytical Chemist.
 Stephens, Alfred, Dinas Silica Works, Kidwelly, South Wales, Manager.
 Stephens, Daniel, The Arlais, Kidwelly, South Wales, Silica Manufacturer.
 Stephens, H. O'Reilly, 191, Aldersgate Street, London, E.C., Writing Ink Manufacturer.
 Stephens, M. E., Avenue House, Finchley, N., Ink Manufacturer.
 Stephens, H. Chas., M.P., Avenue House, Finchley, N., Ink Manufacturer.
 Stern, Arthur L., 170, Ashby Road, Barton-on-Trent, Brewing Chemist.
 Stewart, D. R., Broxburn, near Edinburgh, N.B., Oilworks Chemist.
 Stevens, Jno. H., The Celluloid Co., Newark, N.J., U.S.A., Manufacturing Chemist.
 Stevens, Wm., The Native Gnano Co., Ltd., 29, New Bridge Street, Blackfriars, E.C., Secretary.
 Stevens, W. J., Rathmines, Brecknock Road, Knowle, Bristol, Technical Chemist.
 Stevenson, Jas., 23, West Nile Street, Glasgow; and The Bromfields, Largs, N.B., Manufacturing Chemist.
 Stevenson, Jno., 219, Burdett Road, Bow, E., Chemist.
 Stevenson, J. C., M.P., 33, Devonshire Place, W., Alkali Manufacturer.
 Stevenson, Dr. T., Guy's Hospital, London, S.E., Chemical Lecturer.
 Stevenson, W., Standard Works, 95A, Southwark Street, London, S.E., Chemical Manufacturer.
 Stewart, Alex. F., 146, Darnley Street, Pollokshields, Glasgow, Assayer.
 Stewart, Ebenezer, Oil Seed Mills, Rochester, Kent, Seed Crusher.
 Stewart, Jeffrey, 15, Claremont Road, Forest Gate, Essex, Sugar Works Manager.
 Stewart, Robt., c/o Boake, Roberts, and Co., Warton Road, Stratford, E., Chemical Works Manager.
 Stewart, S., Casilla de Correo 298, Buenos Ayres, South America, Technical Chemist.
 Stillman, Dr. T. B., Stevens Institute of Technology, Hoboken, N.J., U.S.A., Professor of Analytical Chemistry.
 Stillwell, Chas. M., 55, Fulton Street, New York, U.S.A., Analytical and Consulting Chemist.
 Stirk, Jos., Ferncliffe, Elm Bank, Nottingham, Brewer's Engineer.
 Stock, F. W., Keating, Birchfield, Darlington, Analytical and Consulting Chemist.
 Stockdale, Wm., Irwell Printworks, Stacksteads, near Manchester, Calico Printer.
 Stocks, H. B., 18, Manor Road, Churchtown, Southport, Analytical Chemist.
 Stoddart, F. Wallis, Western Counties Laboratory, Bristol, Analytical Chemist.
 Stoer, J., 6, Hanover Quay, Dublin.
 Stoker, G. N., Laboratory, Somerset House, London, W.C., Analytical Chemist.

- Stone, Frank, Laboratory, Department of Mines and Water Supply, Spencer Street, Melbourne, Victoria, Analytical Chemist and Assayer.
- Stone, F. B., Earldy Villa, Picardy Hill, Belvedere, Kent, Technical Chemist.
- Stone, Thos. W., Chemical Works, St. George, Bristol, Chemical Manufacturer.
- Storer, Dr. John, 29, Bligh Street (G.P. Box 220), Sydney, New South Wales, Consulting Chemist.
- Storey, I. H., Haverbreaks, Lancaster, Chemical Manufacturer.
- Stott, Jno. W., 2, Prince of Wales Road, Swansea, Pharmaceutical Chemist.
- Stowe, W. T., Inland Revenue, Wellington, Salop, Analytical Chemist.
- Strangman, J. Pim, Bleacher.
- Strong, Colin R., 18, Exchange Street, Manchester, Oil Merchant.
- Stuart, C. E., 29, Mosley Street, Newcastle-on-Tyne, Chemical Apparatus Dealer.
- Stuart, Jas., 22, High Street, Hull, Seed Crusher and Oil Refiner.
- Stuart, T. W., 7, Livingston Drive, Sefton Park, Liverpool, Alkali Works Manager.
- Studer, Dr. A., 10, Marsden Street, Manchester, Consulting Chemist.
- Studer, Simon J., 17, Lovely Lane, Warrington, Technical Chemist.
- Sudborough, Dr. J. J., University College, Nottingham, Lecturer in Chemistry.
- Sulman, H. L., 60, Gracechurch Street, London, E.C., Chemist and Metallurgist.
- Summers, Bertrand S., c/o The Western Electric Co., 227, South Clinton Street, Chicago, Ill., U.S.A., Electro-Chemist.
- Sumner, Harold, Butt Hill, Prestwich, Manchester, Dyer and Bleacher.
- Sundström, Karl J., Trenton, Wayne Co., Mich., U.S.A., Manufacturing Chemist.
- Sutherland, D. A., 28, Victoria Street, Westminster, S.W., Consulting Technical Chemist and Assayer.
- Sutherland, Geo., Croft Cottage, Bonhill, N.B., Chemist.
- Sutherland, R. M., Lime Wharf Chemical Works, Falkirk, N.B., Chemical Manufacturer.
- Sutton, F., London Street, Norwich, Analytical Chemist.
- Sutton, F. Napier, 6, Grosvenor Gardens, Willesden Green, N.W., Alkali Works Inspector.
- Swan, David, The Swan Colour Co., Lim., Petershill Road, Glasgow, Colour Manufacturer.
- Swan, J. Cameron, 4, Nicholas Buildings, Newcastle-on-Tyne, Manufacturing Chemist.
- Swan, J. W., 58, Holland Park, London, W., Chemist and Electrician.
- Swinburne, Geo., c/o J. Coates & Co., Planet Chambers, 8, Collins Street East, Melbourne, Australia; (subs.) Suffolk House, Laurence Pountney Hill, E.C., Gas Engineer.
- Swinscoe, John A., c/o The Irish National Condensed Milk Co., Ltd., Clonmel, Ireland, Technical Chemist.
- Sykes, E., 111, Victoria Street, Newtown, Hyde, Cheshire, Technical Chemist.
- Sykes, James, Springfield Soapworks, Heckmoudwike, Soap and Chemical Manufacturer.
- Syme, W. B., c/o Young's Paraffin Oil Co., Addiewell, West Calder, N.B., Oil Works Chemist.
- Tasker, G., 1048, Cathcart Road, Mount Florida, Glasgow, Analytical Chemist.
- Tate, F. H., 9, Hackson Hey, Liverpool, Analytical and Technical Chemist.
- Tate, H., jun., Allerton Beeches, Allerton, near Liverpool, Sugar Refiner.
- Tatlock, J., 40, Renfrew Street, Glasgow, Laboratory Furnisher.
- Tatlock, R. R., 156, Bath Street, Glasgow, Consulting Chemist.
- Tatton, Reginald, A., 44, Mosley Street, Manchester, Civil Engineer.
- Taubman, R., 124, Southampton Row, London, W.C., Analytical Chemist.
- Taylor, Albert, Technical School, Stockport, Lecturer in Chemistry and Dyeing.
- Taylor, Andrew, 11, Lutton Place, Edinburgh, Manufacturing Chemist.
- Taylor, C., Friars Field Villas, Uttoxeter New Road, Derby, Engineer.
- Taylor, Edwin, 146, Hooper Street, Brooklyn, N.Y., U.S.A., Explosives Chemist.
- Taylor, G. Crosland, Ravenscar, Helsby, near Warrington, Electrical Engineer.
- Taylor, G. Midgley, 27, Great George Street, Westminster, S.W., Analytical Chemist.
- Taylor, G. W., Dinting Vale Printworks, Dinting, near Manchester, Printworks Chemist.
- Taylor, H. E., c/o British White Lead Co., Northfleet, Kent, Lead Works Manager.
- Taylor, Jas., Department of Mines, Sydney, N.S.W., Government Metallurgist.
- Taylor, Jas. Davis, 9, Mineing Lane, London, E.C., Chemical Merchant.
- Taylor, Jno., 15, Lucius Street, Torquay, Devon, Pharmaceutical Chemist.
- Taylor, J. Scott, c/o Winsor and Newton, Limited, 38, Rathbone Place, London, W., Technical Chemist.
- Taylor, R. L., 37, Mayfield Road, Whalley Range, Manchester, Analytical Chemist.
- Taylor, Thos., Walmsley Bleach and Dyeworks, near Bury, Lancashire, Bleacher and Dyer.
- Taylor, W. Ambrose, Madron, Penzance, Cornwall, Chemical Apparatus Maker.
- Taylor, W. G. H., 68, Woodlands Road, Ilford, Essex, Analytical Chemist.
- Taylor, W. J., 55, Forsyth Street, Greenock, N.B., Technical Chemist.
- Tchaykovsky, N. W., Langham House, Harrow-on-the-Hill, Consulting Chemist.
- Teahy, G. W. A., Laboratory, 65, Bath Row, Birmingham, Analytical Chemist.
- Teed, Dr. F. L., 15, Victoria Street, Westminster, London, S.W., Analytical Chemist.
- Tennant, Sir Chas., Bart., 35, Grosvenor Square, S.W.; and Glen, Peebleshire, N.B. (Journals to St. Rollox, Glasgow), Alkali Manufacturer.
- Tennant, Jas., Dartmouth Lodge, Saltwell, Gateshead-on-Tyne, Alkali Manufacturer.
- Terry, Albert, Verulam, Mount Albert Road, Balwyn, near Melbourne, Victoria, Brewer.
- Terry, Hubert L., 14, Herbert Street, Moss Side, Manchester, Technical Chemist.
- Tervet, R., 54, Penshurst Road, South Hackney, E., Oil Works Manager.
- Tetley, C. F., Messrs. Jos. Tetley and Son, The Brewery, Leeds, Brewer.
- Thackray, R. B., Leather Works, Newlay, Leeds, Leather Manufacturer.
- Thew, Walter H., Talbot House, Arundel Street, Strand, W.C., Provision Merchant.
- Thomas, C., Pitch and Pay, Stoke Bishop, near Bristol, Soap Manufacturer; Deputy Chairman, Midland Railway.
- Thomas, Edward, 107, Disraeli Road, Putney, S.W., Chemist.
- Thomas, H. Russell, Broad Plain Soap Works, Bristol, Soap Manufacturer.
- Thomas, J., Brook House, Wooburn, near Beaconsfield, Paper Maker.

- Thomas, J. W., Drumpellier, Brunswick Road, Gloucester, Analytical Chemist.
- Thomas, R. Schofield, 48-49, Worcester Street, Wolverhampton, Chemical Merchant.
- Thomas, Philip A., Cornwall Buildings, 35, Queen Victoria Street, London, E.C., Engineer.
- Thomas, S. Percy, 105, Clova Road, Forest Gate, E., Technical Chemist.
- Thomasson, Wm., 167, North Road, St. Helens, Lancashire, Chemist.
- Thompson, Prof. Claude M., University College, Cardiff, Professor of Chemistry.
- Thompson, G. Rudd, 57, Dock Street, Newport, Mon., Analytical and Consulting Chemist.
- Thompson, Gustave W., c/o National Lead Co., Marshall Street, Brooklyn, N.Y., U.S.A., Chemist.
- Thompson, W., jun., Larkfield, Earlestown, Lancashire, Sugar Refiner.
- Thompson, W. G., Tonge Springs Works, Middleton, near Manchester, Colour Manufacturer.
- Thompson, W. P., Patent Office, 6, Lord Street, Liverpool, Patent Agent.
- Thomson, Alonzo L., 16, West Madison Street, Baltimore, Md., U.S.A., Manufacturing Chemist.
- Thomson, Dr. Andrew, 10, Pitcullen Terrace, Perth, Chemical Lecturer.
- Thomson, G. Carruthers, 23, Kersland Terrace, Hillhead, Glasgow, Engineer.
- Thomson, Jas. M., Royal Gunpowder Factory, Waltham Abbey, Essex, Manager (Cordite Branch).
- Thomson, John, 70A, Grosvenor Street, London, W., Photographer.
- Thomson, John, The Grange, Buckton Vale, Stalybridge, Printworks Manager.
- Thomson, J. S., c/o Messrs. Grieve and Co., West Tower Street, Carlisle, Technical Chemist.
- Thomson, Robt. T., 156, Bath Street, Glasgow, Analytical Chemist.
- Thomson, W., Royal Institution, Manchester, Analytical and Consulting Chemist.
- Thomson, Wm. Thos., Royal Gunpowder Factory, Waltham Abbey, Essex, Explosives Chemist.
- Thorne, Dr. L. T., 8, Dynevor Road, Richmond-on-Thames; and (Journals) Southampton Wharf, Battersea, S.W., Technical Chemist.
- Thornycroft, Wallace, 140, Hope Street, Glasgow, Technical chemist.
- Thornton, Christopher, Allen's Printworks, Providence, R.I., U.S.A., Printworks Manager.
- Thornton, David H., Brookfoot Dyeworks, Brighouse, Yorks, Dyer.
- Thornton, H., 5, George Street, Euston Road, N.W., Analytical Chemist.
- Thorp, Frank H., Mass. Inst. of Technology, Boston, Mass., U.S.A., Instructor in Industrial Chemistry.
- Thorp, G. H., Clowes Villa, Lower Broughton, Manchester, Engineer.
- Thorpe, Dr. T. E., F.R.S., Government Laboratory, Somerset House, W.C.; and (Journals) 61, Ladbrooke Grove, Notting Hill, W., Chief Chemist (Customs and Inland Revenue).
- Thorp, W., 24, Crouch Hall Road, Crouch End, N., Paint Manufacturer.
- Tilden, Prof. W. A., F.R.S., 9, Ladbrooke Gardens, Notting Hill, W., Professor of Chemistry.
- Timmins, A., Argyll Lodge, Higher Runcorn, Civil Engineer.
- Timmis, T. Sutton, Widnes, Chemical Manufacturer.
- Tinsley, John D., Miller School, Crozet, Va., U.S.A., Professor of Chemistry.
- Tipler, Fred. C., 7, Richard Street, Crewe, Analytical Chemist.
- Tobey, C. H., Collingwood, Ontario, Canada, Tannery Chemist.
- Toeh, Maximilian, 2364, Seventh Avenue, New York City, U.S.A., Color Merchant.
- Tocher, Jas. F., 1, Chapel Street, Peterhead, N.B., Pharmaceutical Chemist.
- Todd, A. M., 204, North Rose Street, Kalamazoo, Mich., U.S.A., Manufacturing Chemist.
- Todd, Herbert C., 18, Bread Street Hill, London, E.C., Ink and Sealing Wax Manufacturer.
- Tompkins, H. K., 52, Whiteley Road, Gipsy Hill, S.W., Metallurgical Chemist.
- Toms, F. Woodland, States Analyst's Office, St. Heliers, Jersey, Analytical Chemist.
- Tonkin, John, 25A, East 34th Street, Bayonne City, N.J., U.S.A., Manufacturing Chemist.
- Tonks, E., Packwood, Knowle, near Birmingham, Brass Founder.
- Tothill, M. A. L., c/o Castle Chemical Co., Cape Town, S. Africa, Manufacturing Chemist.
- Towers, J. W., Brantwood, Allerton, near Liverpool, Analytical Chemist.
- Towner, Rev. Geo., Carpenters Company's Institute, Stratford, E., Head Master of Organised Science School.
- Townsend, Chas. F., 31, Elms Road, Clapham Common, S.W., Chemist.
- Townsend, Chas. W., 19, Crawford Street, Port Dundas, Glasgow, Chemical Manufacturer.
- Townsend, Oliver C., Port Dundas, Glasgow, Chemical Manufacturer.
- Traphagen, Dr. Frank W., Montana Agricultural Experimental Station, Bozeman, Mont., U.S.A., Chief Chemist.
- Travers, Morris W., 2, Phillimore Gardens, Kensington, W., Chemist.
- Trechmann, A. O., Tinnoth House, Cuxton, near Rochester, Cement Works Chemist.
- Trechmann, Dr. C. O., Warren Cement Works, Hartlepool, Cement Manufacturer.
- Treharne, F. Gwilym, Wrangbrook, Llanishen, near Cardiff, Analytical Chemist.
- Trench, G., Standard House, Faversham, Kent; and the Cotton Powder Co., Limited, Faversham, Explosives Works Manager.
- Trewby, Herbert, Radnor House, Ribblesdale Road, Hornsey, N., Analytical Chemist.
- Tribe, P. C. M., Oswego, New York, U.S.A., Secretary.
- Trimble, Prof. H., 115, North 10th Street, Philadelphia, U.S.A., Professor of Chemistry.
- Trimmell, C. H., Elmhurst, Malden, Surrey, Manufacturing Chemist.
- Trobridge, A., c/o Oldbury Alkali Co., Ltd., Oldbury, Birmingham, Technical Chemist.
- Trubshawe, Wolstan, 6, St. Benet Place, London, E.C., Mining Agent.
- Tubby, Charles, 20, High Street, Manchester, Chemical Manufacturer.
- Tsukiyama, S., Printing Department, Ministry of Finance, Tokyo, Japan, Paper Mills Chemist.
- Tucker, Alex. E., 35, Paradise Street, Birmingham, Metallurgist and Chemist.
- Tucker, Prof. G. R., City Hospital, Boston, Mass., U.S.A., Professor of Chemistry (Massachusetts College of Pharmacy).
- Tuer, Arthur H., Thornhill, near Wigan, Analytical Chemist.
- Tulloch, John, 11, Newton Terrace, Hebburn-on-Tyne, Analytical Chemist.
- Turnbull, G. W., 14, Scotland Road, Carnforth, Lancashire, Metallurgical Chemist.
- Turnbull, Wm., 14, Wilberforce Terrace, Gateshead-on-Tyne, Manufacturing Chemist.
- Turnbull, W. S., Place of Bonhill, Renton, Dumbartonshire, Chemical Manufacturer.
- Turner, H. B. H., 4, Calverley Terrace, Tunbridge Wells, Sugar Refiner.
- Turner, Thos., County Offices, Stafford, Metallurgist and Director of Technical Education.
- Turney, Sir J., Springfield, Alexandra Park, Nottingham, Tanner.
- Turri, Geo. G., Sun Buildings, Queen Street, Melbourne, Victoria, Patent Agent.
- Tweedy, Jas., 77, Western Road, Jarrow-on-Tyne, Metallurgical Chemist.
- Twitchell, E., 10, Bellevue Avenue, Mount Auburn, Cincinnati, Ohio, U.S.A., Candle Works Manager.

Twynam, T., Elmhurst, Egham Hill, Surrey, Metallurgist.
 Typke, P. G. W., Ravenhurst, Norbiton Park, New Malden, Surrey, Chemical Manufacturer.
 Tyrer, Chas. T., Stirling Chemical Works, Stratford, E., Manufacturing Chemist.
 Tyrer, T., Stirling Chemical Works, Stratford, E., Chemical Manufacturer.

U

Ublig, E. C., P.O. Box 46, Millville, Cumberland Co., N.J., U.S.A., Glass Works Chemist.
 Umney, C., 50, Southwark Street, London, S.E., Manufacturing Chemist.
 Underhill, Thos. J., I.M. Victualling Yard, Deptford, S.E., Assistant Inspector of Stores.
 Underwood, G. R., Box 460, Peabody, Mass., U.S.A., Glue Works Chemist.
 Urquhart, David, 17, Victoria Street, Westminster, S.W., Electrical Engineer.
 Usmar, J. H., 22, Billiter Street, London, E.C., Chemical Merchant.
 Utsumi, S., c/o Gakushikwai, Imperial University, Hongo, Tokio, Japan, Technical Chemist.

V

Vandenbergh, Dr. Frank P., 32-33, Lewis Block, Buffalo, N.Y., U.S.A., Professor of Chemistry.
 Vanderpool, Dr. Frank, 191, Roseville Avenue, Newark, N.J., U.S.A., Chemist.
 Van Gundy, Chas. P., Laboratory, B. & O. R. R., Baltimore, Md., U.S.A., Metallurgical Chemist.
 Vargas-Vergara, J. M., Apartado No. 237, Bogota, Republic of Colombia, S. America, Metallurgical Chemist.
 Vary, G. M. P., 1319, O'Farrell Street, San Francisco, Cal., U.S.A., Analytical Chemist.
 Vasey, T. E., 6, South Parade, Leeds; Journals to P.O. Box 1449, Montreal, Canada, Chemical Engineer.
 Vaughan, J. L., 329, Norwood Road, Tulse Hill, S.E., Chemical Works Manager.
 Vautin, Claude T. J., 42, Old Broad Street, London, E.C., Metallurgist.
 Veitch, Geo., Chemical Works, Crieff, N.B., Manufacturing Chemist.
 Veitch-Wilson, J., 8, Earlsfield Road, Wandsworth Common, S.W., Oil Refiner.
 Verel, W. A., 136, West George Street, Glasgow.
 Vickers, W., Rose Hill, Smedley Lane, Manchester, Chemical Manufacturer.
 Vigelius, Carl, 175, Pearl Street, New York City, U.S.A., Shellac Bleacher.
 Voelcker, E. W., 22, Tudor Street, London, E.C., Agricultural Chemist.
 Voelcker, Dr. J. A., 20, Upper Phillimore Gardens, Kensington, W., Agricultural Chemist.
 Vorster, Fritz, 71, Bayenstrasse, Cöln a/Rhein, Germany, Manufacturing Chemist.
 Voss, Hermann, 19, Beckenham Road, Beckenham, Kent, Manure Works Manager.
 Vulté, Hermann T., School of Mines, Columbia College, New York, U.S.A., Analytical Chemist.

W

Waché, Alf., 27, Rue Morel, Douai, France, Caustic Potash Manufacturer.
 Waddington, Thos. W., 8, Albert Street, Padiham, Lancashire, River Inspector.

Wade, Jas. L., 28, West Kensington Gardens, London, W., Chemical Manufacturer.
 Wade, John, 48, Gordon Mansions, Gower Street, London, W.C., Demonstrator of Chemistry.
 Wade, W. L., 28, West Kensington Gardens, W., and (Journals) Staines Linoleum Works, Staines, Chemist.
 Wadman, W. E., 102, Lord Avenue, Bayonne, N.J., U.S.A., Manufacturing Chemist.
 Wagner, W. G., Glyndhurst, Ealing Common, W., Analytical and Consulting Chemist.
 Wainwright, Dr. J. H., 22, West 46th Street, New York, U.S.A., Analytical Chemist.
 Wainwright, Wm., c/o Dublin and Wicklow Manure Co., Ltd., Ballybough, Dublin, Chemist.
 Waldman, Louis J., P.O. Box 162, Albany, N.Y., U.S.A., Aniline Dye Manufacturer.
 Waldstein, Dr. Martin E., 41, Trinity Place, New York, U.S.A., Manufacturing Chemist.
 Walker, A., Messrs. Alex. Walker and Co., Alkali Works, Irvine, N.B., Chemical Manufacturer.
 Walker, Archibald, 8, Crown Terrace, Glasgow, Distiller.
 Walker, E. Robinson, 18, St. Ann's Street, Manchester, Patent Agent.
 Walker, Dr. Jas., University College, Dundee, Professor of Chemistry.
 Walker, S. R., 19, Wolsey Street, Radcliffe, Manchester, Foreman Dyer.
 Walker, T., Eccleston Park, Prescott, Lancashire, Chemical Manufacturer.
 Walker, W. Sloane, Wood Bank, Erith, Kent, Tanner.
 Wallace, Robert, 1, Coates Place, Edinburgh, Distiller.
 Waller, Dr. E., School of Mines, Columbia College, 50th Street, 4th Avenue, New York, U.S.A., Professor of Chemistry.
 Walsh, F. T., Hamilton Printworks, Lowell, Mass., U.S.A., Colour Printer.
 Waltham, T., Brewery, Stockwell, London, S.W., Brewer.
 Walton, F., 114, Holborn, E.C., Inventor and Manufacturer.
 Wander, Dr. A., Chemical Laboratory, Berne, Switzerland, Chemist.
 Want, W. Philip, 42, Bishopsgate Street Without, London, E.C., Pharmacist and Editor.
 Ward, G., Messrs. Hirst, Brooke and Hirst, Leeds, Chemical Works Manager.
 Ward, Geo., c/o T. Howard Lloyd & Co., 86, High Street, Leicester, Technical Chemist.
 Ward, G. J., The Cottage, Hallam Fields, near Nottingham, Civil Engineer.
 Ward, Howard Chas., Yeaton, Hordle, Lymington, Hants, Deputy Chairman of Gas Co.
 Ward, Thos., Wadebrook House, Northwich, Salt Manufacturer.
 Wardale, J. D., Redheugh Engine Works, Gateshead-on-Tyne, Engineer.
 Warden, Dr. C. J. H., Medical College, Calcutta, India, Professor of Chemistry.
 Warden, Jno. B., 5, Eton Gardens, Glasgow, Analytical Chemist.
 Wareing, Arthur E., Bedford House, Appleton, Widnes, Analytical Chemist.
 Warrington, Robt., F.R.S., Harpenden, Herts, Agricultural Chemist.
 Warner, H. G., 5, St. Anne's Park Terrace, Wandsworth, S.W., Chemical Engineer.
 Warren, Fiske, 220, Devonshire Street, Boston, Mass., U.S.A., Paper Manufacturer.
 Warren, Jno. Davis, 7, Essex Road, Acton, W., Manufacturing Chemist.
 Warren, T. T. P., Bruce, Tamworth Villa, Earlham Grove, Forest Gate, Essex, Analytical Chemist.
 Warwick, A. W., The Ninah Mine, Wickes, Montana, U.S.A., Metallurgical Chemist.
 Watel, H. G., Buckhurst Hill, Essex, Consulting Mechanical Engineer.
 Waterfall, W. B., c/o Avon Manure Co., Bristol; and (Journals) Thirlmere, Clavering Road, Redland, Bristol, Manure Manufacturer.
 Waterhouse, Colonel Jas., 14, Wood Street, Calcutta, India, Assistant Surveyor-General of India.

- Waterhouse, Robt., 101, Leadenhall Street, London, E.C., Analytical and Agricultural Chemist.
- Wates, Edw. A., 56, Breakspear's Road, St. John's, S.E., Metallurgical Chemist.
- Watmough, B., c/o Brotherton and Co., Calder Vale Chemical Works, Wakefield, Analytical Chemist.
- Watney, Thos. S., 71, Albion Street, Leeds, Electrical Engineer.
- Watson, Alex. Forbes, 11, York Place, Edinburgh, Assistant (University Laboratory).
- Watson, Chas. Ernest, c/o Peter Spence and Sons, Manchester Alum Works, Manchester, Chemical Assistant.
- Watson, C. Heron, Bullionfield Paper Mill, by Dundee, N.B., Paper Manufacturer.
- Watson, Chas. S., c/o Australian Gold Recovery Co., Charters Towers, Queensland, Analytical Chemist.
- Watson, Chas., Walsden Chemical Works, near Todmorden, Manufacturing Chemist.
- Watson, D., Willow Bank House, Kersal Vale, Manchester, Metallurgist.
- Watson, Eric E., Fundicion y Beneficiadora, Antofagasta, Chili, Metallurgical Chemist.
- Watson, G., 16, East Nelson Street, Whitevale, Glasgow, Manufacturing Chemist.
- Watson, Geo. P., Elm Lodge, Halliwell Lane, Cheetham Hill, Manchester, Printworks Chemist.
- Watson, Henry Ard, 17, Cavendish Road, Leeds, Tar Distiller.
- Watson, Jas., Caldwell, South Shields, Alkali Works Manager.
- Watson, Jno. C., c/o Daniel Lee & Co., Castleton, Manchester, Technical Chemist.
- Watson, Jno., Cement Works, Gateshead-on-Tyne, Cement Manufacturer.
- Watson, Jno., Allhnsen's Works, Gateshead-on-Tyne, Technical Chemist.
- Watson, Jno., 8, Newman Street, Victoria Docks, E., Analytical Chemist.
- Watson, John, Hillside Cottage, Hawick, N.B., Science Student.
- Watt, A., 19, Brompton Avenue, Sefton Park, Liverpool Sugar Works Chemist.
- Watts, A. J., 130, Caixa, Pernambuco, Brazil, Sugar Works Chemist.
- Watts, Chas. W., 40, Goldhurst Terrace, London, N.W., Gasworks Chemist.
- Watts, Jno. Isaac, Fairleigh, Hartford, Cheshire, Alkali Works Manager.
- Webb, Saml. G., 2314, East Grace Street, Richmond, Va., U.S.A., Technical Chemist.
- Webb, Wm. Hubert, Randalstown, co. Antrim, Ireland, Linen Manufacturer.
- Weber, Dr. C. Otto, 2, Randolph Street, Crumpsall, Manchester, Analytical Chemist.
- Webster, C. S., Stamford, Malvern House, Redland, Bristol, Professor of Chemistry.
- Weed, Hy. T., 298, Herkimer Street, Brooklyn, N.Y., U.S.A., Teacher of Chemistry.
- Weeks, H. B., Cossipore, Calcutta, India, Analytical Chemist.
- Weeks, Jos. D., Box 59, Pittsburg, Pa., U.S.A., Editor and Metallurgical Engineer.
- Weems, Dr. J. B., Iowa Agricultural College, Ames, Iowa, U.S.A., Agricultural Chemist.
- Weightman, John F., c/o Powers & Weightman, Philadelphia, Pa., U.S.A., Doctor of Medicine.
- Weir, Surgeon-Major P. A., Quetta, Beloochistan, India, Surgeon.
- Welch, J. Cuthbert, The Brewery, Reading, Berks, Brewer's Chemist.
- Welch, Thos., Green Vale Printworks, Westhoughton, Lancashire, Calico Printer.
- Weldon, Ernest, 300, Radford Road, New Basford, Nottingham, Dyer.
- Wells, G. I. J., 77, Parkgate Road, Chester, Analytical Chemist.
- Wells, Jas. Gray, Solwood House, Shobnall Street, Burton-on-Trent, Brewing Chemist.
- Wells, Pierson L., 86, Jerusalem Street, Brooklyn, N.Y., U.S.A., Patent Lawyer and Engineer.
- Welsh, Jas., Horrocks Lane Dyeworks, Red Bank, Manchester, Printworks Manager.
- Welsh, Thos. L., 3, Prince's Gardens, Dowanhill, Glasgow, Analytical Chemist.
- Welsh, W., Holt Town, Manchester.
- Werner, Emil A., 5, Church Avenue, Rathmines, Dublin, Chemical Demonstrator.
- Wessel, Carl, Bernburg, Anhalt, Germany, Alkali Manufacturer.
- Wesson, D., c/o The Wesson - Nivison Manufacturing Co., Cortlandt, N.Y., U.S.A., Consulting Technical Chemist.
- Westenfelder, B. D., c/o American Oak Leather Co., Cincinnati, Ohio, U.S.A., Leather Chemist.
- Westmoreland, J. W., 2, City Road, Finsbury Square, E.C., Metallurgical Chemist.
- Weston, Robt. S., Box 614, Louisville, Ky., U.S.A., Technical Chemist.
- Weston, Wm., H.M. Dockyard, Portsmouth, Analytical Chemist.
- Wetter, Jasper, 433, Strand, London, W.C., Patent Agent.
- Wetzel, H. A., Box 470, Detroit, Michigan, U.S.A., Manufacturing Chemist.
- Whalley, L. J. de, 26, Park Place, Greenwich, S.E., Sugar Chemist.
- Wheelwright, Dr. E. W., The Oaklands, Warley, Oldbury, near Birmingham.
- Whiffen, T., Lombard Road, Battersea, London, S.W., Manufacturing Chemist.
- Whiffen, T. jun., Lombard Road, Battersea, London, S.W., Manufacturing Chemist.
- Whiffen, W. G., Lombard Road, Battersea, London, S.W., Manufacturing Chemist.
- Whitaker, Alf. Waltham, Horsforth, Leeds, Dyer.
- Whitaker, H. L., Condong Sugar Mill, Tweed River, New South Wales, Sugar Chemist.
- Whitaker, Thos., 9, Parliament Hill Road, Hampstead, N.W., Dyer.
- Whitaker, Thorp, Messrs. E. Ripley and Sons, Bradford, Yorks, Dyer's Chemist.
- White, A. D., Avenue House, West Drayton, Middlesex, Chemical Manufacturer.
- White, Arthur F., 61, Sunbridge Road, Bradford, Yorks, Manufacturing Druggist.
- White, Arthur J., Arison Gold Mine, Klerksdorp, South Africa, Assayer.
- White, B., Newport, Manor Hill, Marple, Cheshire, Consulting Brewer.
- White, G. Rantoul, Exeter, New Hampshire, U.S.A., Chemist.
- White, Henry, 43, Woodstock Road, Sheffield, Manufacturing Chemist.
- White, Jno. Freebairn, c/o Punjom Mining Co., Punjom-Pahang, via Singapore, Chemist.
- White, Jos. Walwyn, Springfield, Farnworth, nr. Widnes, Iron Merchant.
- White, J. Campbell. See Overtoun, Lord.
- White, P. T., Castle Street, Saffron Hill, London, E.C., Chemical Manufacturer.
- White, W. Gilchrist, P.O., Broadbottom, near Manchester, Calico Printer's Chemist.
- White, W. H., The Cottage, Killingworth, Newcastle-on-Tyne, Chemical Manufacturer.
- White, Wm. T., Messrs. White Bros. & Co., Box 45, Lowell, Mass., U.S.A., Leather Manufacturer.
- Whitehead, Catell, 1114, New Hampshire Avenue, Washington, D.C., U.S.A., Assayer (U.S. Mint).
- Whitehead, J., 1, Parkin Lane, Meltham, Huddersfield, Dyer.
- Whitehead, Wm. T., Magog, Prov. Quebec, Canada.
- Whitelaw, T. N., 87, Sydney Street, Glasgow, Soap Manufacturer.
- Whiteley, R. Lloyd, The Institute, West Bromwich, Staffordshire, Chemical Lecturer.
- Whiteside, Jno. L., 51, Cannon Street, Bolton-le-Moors, Chemical Lecturer.
- Whittaker, C. J., Globe Chemical Works, Church, near Accrington, Chemical Engineer.

- Whittaker, Thos., 22, Delaunays Road, Higher Crumpsall, Manchester.
- Whittle, Naylor, Newton Chemical Works, Hyde, near Manchester, Analytical Chemist.
- Whowell, F., Carr Bank, Tottington, Bury, Lancashire, Bleacher.
- Wickens, B. Foster, 83, Queen Street, Cheapside, London, E.C., Secretary and Manager (Wickens, Pease & Co., Lim.).
- Wiggin, W. W., Wiggin Street, Birmingham Heath, Birmingham, Nickel Refiner.
- Wightman, C., 1, Fenchurch Avenue, London, E.C., Chemical Merchant.
- Wilcox, H., Stanford-le-Hope, Essex., Explosives Works Manager.
- Wild, W. E., Ousel Nest Cottage, Bromley Cross, near Bolton, Analytical Chemist.
- Wilder, F. L., Villa Nova de Lima, Estado de Minas Geraes, Brazil, Assayer.
- Wiley, M. W., Billsdale House, York Road, West Hartlepool, Glue Maker.
- Wilkie, T. M., Nobel Co.'s Works, Stevenston, Ayrshire, N.B., Explosives Chemist.
- Wilkin, Sir Walter, Appold Street, Finsbury, E.C., Yeast Manufacturer.
- Wilkins, Charles, 40, Church Lane, Hornsey Old Church, N., Manufacturing Perfumer.
- Wilkinson, Dr. Saml., The Grove Co., Ltd., Marsh Gate Lane, Stratford, E., Analytical Chemist.
- Wilkinson, J. B., Tong Street, Dudley Hill, Bradford, Yorks, Chemical Manufacturer.
- Will, W. Watson, 1, St. Agnes Place, Kennington Park, S.E., Professor of Organic Chemistry.
- Willcox, Benjamin, 47, Lincoln's Inn Fields, London, W.C., Patent Agent.
- Willcox, Oliver, 307, Carroll Street, Brooklyn, N.Y., U.S.A., Technical Chemist.
- Willdigg, A. E., Ford Cottage, Coventry, Varnish Maker.
- Williams, D., 11, Windle Street, St. Helens, Technical Chemist.
- Williams, David T., 22, Morgan Street, Hafod, Swansea, Chemist.
- Williams, Geo. G., 624, South 24th Street, Philadelphia, Pa., U.S.A., Analytical Chemist.
- Williams, Henry J., c/o Davenport and Williams, 161, Tremont Street, Boston, Mass., U.S.A., Chemical Engineer.
- Williams, Percy B., 22, Bisham Gardens, Highgate, N., Chemist.
- Williams, Rowland, Sunny Lea, Aldcliffe Road, Lancaster, Analytical Chemist.
- Williams, R. Greville, Greenfield House, Hopwood, near Manchester, Colour Manufacturer.
- Williams, Seward W., 8, Brighton Avenue, East Orange, N.J., U.S.A., Pharmaceutical Laboratory Manager.
- Williams, T., A, Queen Insurance Buildings, 10, Dale Street, Liverpool, Analytical Chemist.
- Williams, Thos., Marie Rose Mines, Johannesburg, S.A.R., Assayer and Manager.
- Williams, T. Howell. See Idris, T. H. W.
- Williams, Prof. W. Carleton, Firth College, and 23, Broomgrove Road, Sheffield, Professor of Chemistry.
- Williams, W. Collingwood, 68, Grove Street, Liverpool, Analytical Chemist.
- Williams, W. J., 635, Market Street, Camden, N.J., U.S.A., Analytical Chemist.
- Williamson, J. Alex., c/o The British Explosives Syndicate, Ltd., Pitsea, Essex, Analytical Chemist.
- Williamson, Robt., Low Walker, Newcastle-on-Tyne, Technical Chemist.
- Wills, Samuel Day, Castle Green Colour Works, Bristol, Colour and Enamel Manufacturer.
- Willson, Thos. L., 45, Broadway, New York, U.S.A., Electrical Engineer.
- Wilson, A. Poole, c/o Maypole Dairy Co., Knocklong, co. Limerick, Ireland, Analytical Chemist.
- Wilson, Alf., c/o Messrs. J. and E. Sturge, 18, Wheeley's Lane, Birmingham, Manufacturing Chemist.
- Wilson, Anthony W., 20, Westcott Street, Hull, Colour Works Manager.
- Wilson, Cecil H., 31, Minna Road, Burngreave Road, Sheffield, Metallurgical Chemist.
- Wilson, C. J., 14, Old Queen Street, Westminster, S.W.
- Wilson, David, jun., Carbeth, Killearn, by Glasgow.
- Wilson, Frank, The Brewery, Castle Street, Long Acre, London, W.C., Brewer.
- Wilson, G. E., The Chemical Works, Oldbury, near Birmingham, Chemical Manufacturer.
- Wilson, J. Arthur, Vale House, Piercy, Newchurch-in-Rossendale, Assistant Printworks Manager.
- Wilson, Jno. Ed., Wyddrington, Edgbaston, Birmingham, Chemical Manufacturer.
- Wilson, Jno., 28, Crosby Road, Romford Road, Stratford, E., Technical Chemist.
- Wilson, J. H., 6, Fenchurch Buildings, E.C., Chemical Manufacturer.
- Wilson, R. H., Eggescliffe, Yarm-on-Tees, Chemical Manufacturer.
- Wilson, Wesley Wm., Ardganagh, Ballsbridge, Dublin, Civil Engineer.
- Wilson, Dr. W. H., Presidency College, Madras, Lecturer on Physics.
- Wilson, Wm. Robt., 110, Long Acre, London, W.C., Analytical Chemist.
- Wilson, W. W., Rhodes Works, Middleton, Manchester, Analytical Chemist.
- Wilson, Wm., Journals to Delhi, India; Subscription c/o Clark, Wilson, & Co., 11, Abchurch Lane, E.C., Merchant.
- Wilton, Geo., Tar Works, Beckton, E., Tar Distiller.
- Wilton, Jno., Clydesdale, Norwich Road, Forest Gate, Essex, Candle Manufacturer.
- Wilton, Thos., Winsor House, Beckton, E., Tar Works Manager.
- Wing, J. D., 22, William St., New York, U.S.A., Merchant.
- Wingate, Hamilton M., 395, Collins Street, Melbourne, Victoria, Metallurgist.
- Wingfield, T. R., Nelson Square, Bolton, Brewer.
- Wingham, A., 112, Warwick Street, Pimlico, S.W., Metallurgical Chemist.
- Wincer, P. J., Greendale, Port Sunlight, near Birkenhead, Soap Works Manager.
- Winsloe, H., c/o Tennants & Co., Clayton, Manchester, Manufacturing Chemist.
- Winstanley, Hy., Hayfield Printing Co., Hayfield, near Stockport, Calico Printer.
- Winstone, E. H., 2, Victoria Mansions, Victoria Street, London, S.W., Ink and Paint Manufacturer.
- Wirtz, Dr. Quirin, 28, Great Ormond Street, W.C., Consulting Chemist.
- Wichart, Jno., 39, St. Vincent Place, Glasgow, General Manager (Oakbank Oil Co., Lim.).
- Witt, Dr. Otto N. E., Lindénallee 33, Westend, bei Berlin Professor of Chemistry.
- Witthaus, Dr. R. A., 303, West 77th Street, New York City, U.S.A., Professor of Chemistry.
- Woltreck, Dr. H. C., 35, Wall Street, New York City, U.S.A., Consulting Chemist.
- Wood, Ebenezer, Stephenson Street, Canning Town, E., Manufacturing Chemist.
- Wood, Jos. T., 29, Musters Road, West Bridgeford, Nottingham, Tanner.
- Wood, Robt. B., Dalquhurn Works, Renton, N.B., Dyeworks Chemist.
- Wood, Wm., 128, Chaussée de Turnhout, Antwerp, Belgium, Bleacher and Dyer.
- Wood, W. Copland, Rosshead, Alexandria, Dumbarton, shire, Turkey Red Dyer.
- Wood, W. H., 3, New Road, Halifax, Yorks, Chemist.
- Woodcock, R. C., American and Continental Sanitas Co., 636-642, West 55th Street, New York, U.S.A., Technical Chemist.
- Woodham, Kingston G., 5, Lethbridge Road, Southport, Oilworks Manager.
- Woodhead, Jas., Inglewood, Slaithwaite, near Huddersfield, Tar Distiller.

Woodman, Dr. Durand, 80, Beaver Street, and 127, Pearl Street, New York, U.S.A., Analytical Chemist.

Woodward, W. C., Biddulph Valley Coal and Iron Works, Stoke-on-Trent, Ironmaster.

Woofindale, Chas. S., c/o Silver Spring Bleaching and Dyeing Co., Providence, R.I., U.S.A., Dyeworks Manager.

Woolf, Julian, 1, Marlborough Place, St. John's Wood, N.W., Manufacturer.

Woolf, Mortimer, Messrs. Yeatman and Co., Denmark Street, E.; and (Journals), 16, Greville Place, London, N.W., Vinegar Brewer and Manufacturer of Food Products.

Woolcombe, Dr. Robert Lloyd, 14, Waterloo Road, Dublin, Barrister-at-Law.

Woolley, G. S., Victoria Bridge, Manchester, Pharmaceutical Chemist.

Woolworth, J. G., 246, Fountain Street, Providence, R.I., U.S.A., Consulting Chemist.

Worms, Emil, Elaboug, Govt. of Viatka, Russia, Technical Chemist.

Worrall, H., Crimsworth, Whalley Range, Manchester, Dyer.

Worsley, P. J., Rodney Lodge, Clifton, Bristol, Chemical Manufacturer.

Worth, F. G., 63, Queen Victoria Street, London, E.C., Managing Director.

Wotherspoon, Peter, 14, Prospect Terrace, Jarrow-on-Tyne, Chemist.

Wray, O. J. P., 17, Old Dover Road, Blackheath, Works Chemist (British Alizarine Co., Ltd.).

Wright, Alf., The Medical Hall, Yeovil, Pharmaceutical Chemist.

Wright, Arthur C., The Yorkshire College, Leeds, Demonstrator.

Wright, Jos., 19, Arboretum Street, Nottingham, Lace Dresser.

Wright, L. T., 1, Victoria Street, Westminster, S.W., Gas Engineer.

Wright, Sidney B., Lancarfe, Albemarle Road, Beckenham, Kent, Analytical Chemist.

Wülfing, Dr. Charles, District Chemical Works, North Woolwich, E., Technical Chemist.

Wyatt, Dr. Francis, 12, Old Slip, New York, U.S.A., Consulting Chemist.

Wyld, J., Nechells Park Chemical Works, Birmingham, Chemical Works Manager.

Wylde, J. R., Hill House, Wavertree, near Liverpool, Analytical Chemist.

Y

Yates, F., 64, Park Street, Southwark, London, S.E., Chemical Manufacturer.

Yates, R., 64, Park Street, Southwark, London, S.E., Chemical Manufacturer.

Yocum, Dr. Jno. H., 28, Ferry Street, New York, U.S.A., Chemist.

Yoshida, Hikokuro, Imperial University, Hongo, Tokyo, Japan, Professor of Chemistry.

Young, A. C., 64, Tyrwhitt Road, St. John's, S.E.

Young, Brongham, Analytical Chemist.

Young, Dr. Geo., Firth College, Sheffield, Chemist.

Young, Jno., 2, Montague Terrace, Kelvinside, Glasgow, Technical Chemist.

Young, Jno., Gasworks, Etruria, near Stoke-on-Trent, Gas Engineer.

Young, Jno., The Linlithgow Oil Co., Ltd., 123, Hope Street, Glasgow, Oil Co.'s Manager.

Young, Dr. Sydney, 13, Aberdeen Terrace, White Ladies Road, Bristol, Professor of Chemistry.

Young, T. Graham, Westfield, West Calder, N.B., Technical Chemist.

Young, W. C., Chemical Laboratory, 19 and 20, Aldgate, London, E.C., Gas Examiner and Consulting Chemist.

Young, Wm., Priorsford, Peebles, N.B., Chemical Engineer.

Z

Zimmermann, A., 6/7, Cross Lane, St. Mary-at-Hill, London, E.C., Chemical Agent.

Zinkeisen, Dr. W., 225, George Street, Glasgow; and (Journals), Cauca Gold Estates Lim., Cali, Colombia, South America, Analytical Chemist.

Zocler, E. V., Tarboro', North Carolina, U.S.A., Cotton Seed Oil Refiner and Pharmacist.

Zurborn, Otto, Grevenbroich, Rheinprovinz, Germany, Engineer.

THE JOURNAL

OF THE

Society of Chemical Industry.

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 2.—VOL. XV.]

FEBRUARY 29, 1896.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, Bart., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
Dr. W. H. Perkin, F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.
Sir John Evans, K.C.B., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
Dr. T. E. Thorpe, LL.D., F.R.S.	1894—1895.

COUNCIL FOR YEAR ENDING JULY, 1896.

President: Thos. Tyrer.

Vice-Presidents:

Sir F. A. Abel, Bart., F.R.S.	T. Fairley.
Herace T. Brown, F.R.S.	Boverton Redwood.
John Calderwood.	Sir H. E. Roscoe, M.P., F.R.S.
Chas. Dreyfus.	E. C. C. Stanford.
Dr. A. Dupré, F.R.S.	Dr. T. E. Thorpe, LL.D., F.R.S.
Sir John Evans, K.C.B., F.R.S.	Prof. W. A. Tilden, F.R.S.

Ordinary Members of Council:

J. S. MacArthur.	C. C. Hutchinson.
C. A. Fawsitt.	Ivan Levinstein.
R. Le Neve Foster.	Sir Robt. Pullar.
W. Douglas Herman.	G. N. Stoker.
David Howard.	Wm. Thorp, B.Sc.
Prof. A. K. Huntington.	Frank Wilson.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors:

L. Archbutt, L., XII., XVIII. B.	W. Macnab, XXII.

John Heron.	H. R. Precter.
D. B. Hewitt, M.D.	Boverton Redwood.
David Howard.	Walter F. Reid.
Prof. J. J. Hummel.	John Spiller.
Prof. A. K. Huntington.	Wm. Thorp.
P. Hurter, Ph.D.	Lewis T. Wright.

NOTICES.

Notice is hereby given that, in accordance with the alterations in Rule 27 sanctioned at the Annual General Meeting in Edinburgh, all new members elected after January 1st, 1895, will be required to pay an entrance fee of one guinea. In accordance with the same rule the Life Composition Fee is now 20*l.*, instead of 15*l.* as heretofore.

COLLECTIVE INDEX.

A collective index, embracing the whole Journal from the Proceedings of the First Annual General Meeting, 1881, to the close of 1895, is now in preparation, and will be ready in the current year. It will contain both a subject-matter and authors' names portion and will be a volume of about 500 pages uniform in size with the Journal.

The prices will be as follows:—

To Members (see Rules 25 and 27) who make application with remittance, not later than June 30, 1896.....	Each copy	5s.
To Members (see Rules 25 and 27) who make later application; Libraries, Corporations, and Exchanges on the Society's List, and Past Members (see Rule 30)	Each copy	10s.
To Subscribers	„	12s. 6d.
To others.....	„	15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. **EXNE and SPOTTISWOODE**, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

MEMORIAL TO THE LATE PROF. HUXLEY, F.R.S.

This Memorial will take the form of a statue to be placed in the Museum of Natural History, and a medal in connection with the Royal College of Science, while the surplus will be devoted to the furtherance of biological science. Donations towards the fund should be sent to Mr. G. B. Howes, Hon. Sec. Huxley Memorial Committee, Royal College of Science, South Kensington, S.W.

LIST OF MEMBERS ELECTED 21st FEBRUARY 1896.

Akeroyd, F. W., Grosvenor Villa, Batley, Yorks, Oil Refiner.
 Billings, Edgar F., 165, High Street, Boston, Mass., U.S.A., Manufacturing Chemist.
 Bragg, Everett B., 242, Kennard Street, Cleveland, Ohio, U.S.A., Manufacturing Chemist.
 Bray, Geo., Bagby Fields, Leeds, Gas Lighting Engineer.
 Cobleigh, W. M., Bozeman, Mont., U.S.A., Assistant Chemist (State College of Agriculture).
 Crosby, Thos., c/o W. D. Houghton, Sankey Wire Mills, Warrington, Metallurgist.
 Evans, Dr. Thos., c/o American Cotton Oil Co., 46, Cedar Street, New York, U.S.A., Chief Chemist.
 Fox, A. Stanley, 23, South Road, Faversham, Kent, Chemist (Cotton Powder Co., Limited).
 Gardair, Aimé, 51, Rue St. Ferréol, Marseilles, France, Director of Chemical Co.
 Glover, H., East Falls, Schuylkill, Philadelphia, Pa., U.S.A., Chemical Works Superintendent.
 Harris, Wm. T. A., 18, Crescent Place, Hackney Road, E., Soap Maker.
 Haynes, Geo., 12, Ince Avenue, Litherland, Liverpool, Sub-manager (Gas Works).
 Hislop, Geo. B., Gas Work House, Craigielea, Paisley, N.B., Gas Engineer and Manager.
 Hogg, Alex. F., 73, Stanhope Road, Darlington, Teacher of Chemistry.
 Kalbfleisch, Franklin H., 80-82, William Street, New York, U.S.A., Chemical Manufacturer.

SESSION 1895-96.

Monday, March 2nd, 1896.—Messrs. Cross and Bevan. "The Manufacture of Artificial Silk."
Monday, April 13th, 1896.—Mr. R. W. Sindall. "Moisture in Wood Pulp."

Meeting held Monday, January 6th, 1896.

MR. B. E. R. NEWLANDS IN THE CHAIR.

THE EFFECT OF LIME SALTS ON HOP INFUSIONS.

BY JOSEPH W. LOVIDOND.

In most manufactures, at various stages, chemical and other changes take place, which, though clearly indicated by change of colour in the material and reckoned as important factors in the quality of the ultimate product, are too subtle for the balance of the analytical chemist.

As an example for illustrating the importance of these obscure changes, I have selected the phenomena attending the boiling of hops in water containing calcium bicarbonate and other salts in solution, not only because of the distinctive colours produced, but also because in my past brewing experience a specially undesirable flavour was noticed in beer brewed with water drawn from a deep chalk well, and containing calcium bicarbonate in solution, which led to the rule of first boiling the water and then allowing it to cool to the desired temperature for mashing. The soundness of this empirical practice will be evident when we come to compare the difference between the specific colour curves of a similar water before and after boiling. There is but little doubt that colour variations are attended by co-related variations in flavour, although no attempt is here made to establish such co-relations, as such a course would involve a more extensive set of investigations than was possible in the time available for preparing this paper.

The effect of the earthy salts usually present in ordinary brewing water has received but little attention, and, so far as I have been able to ascertain, none at all from an analytical point of view.

The authorities on the subject are few. "Science Pratique du Brassayr," by Johnson Freuk and Dr. Henin, edition 1890, mentions some advantages of the use of water containing lime salts in solution, but make no reference to the colour effect.

Southby, in his book "Practical Brewing," says, "The presence of the carbonates of the alkalis has an even more injurious effect on the ales, for these salts promote the solution of the colouring matter of both the malt and the hops, and also of the coarse, resinous, bitter principles of the latter. Neither of these salts is so objectionable in black beers as in ales, and some have asserted that waters for brewing stout and porter ought to contain a small proportion of the carbonates of the alkaline carbonates; this, however, is a mistake, as the best waters for brewing black beers are those which contain only carbonates of lime and magnesia, together with some chlorides and minute amounts of earthy sulphates and alkaline silicates."

Moritz and Morris, in "A Text-book of the Science of Brewing," mention the question of colour, and state, "Briefly it may be said that gypseous waters give pale beers and prevent the extraction of the coarse, rank flavour of the hops; sodium carbonate water, on the other hand, gives deeply tinted beers, extracting much of the coarse and rank hop flavouring; soft waters come intermediate between these extremes. Sodium sulphate gives a thin, harsh, cold flavour, but a pale colour. Common salt and calcium chloride also yield pale beers, and the hop flavouring is neither rank nor cold. Magnesium salts are not used apart from gypsum, and their effects alone are therefore unascertained."

Faulkner, in his "Theory and Practice of Modern Brewing," p. 9, states that "the other carbonates, magnesian and calcic, have little or no influence, I think, except in the way of coating our boilers, liquor tanks, and pipes with scale, and neutralising the normal acidity of the malt."

In the American Brewers' Journal for August 1895 appears a paper by Dr. F. Mierau, in which he details some valuable experiments as to the action of calcium hydrate and carbonate upon the colour of hop extract, and gives some elaborate details as to his method of procedure and the results with waters containing different constituents, but in describing the results uses somewhat vague terms, such as "light yellowish fluid," "pale beer," "much paler," "much yellower colour," "strongly coloured fluids of a specific reddish tint," &c. I have adopted Dr. Mierau's method of procedure, not only because of its simplicity and effectiveness, but also because my quantitative colour terms may be used for comparing with Dr. Mierau's results. He describes his method as follows:—

"My method consists of simply boiling the water or salt solutions to be tested with hops. I use beakers of equal size, and in boiling have the heating in the same sand-bath as uniform as possible. To each 100 c.c. of water I take 3 grms. of the same hops, selecting as nearly as possible uniform catkins, which I pick apart and place in the water."

To this method I adhered, but found it necessary after 30 minutes' boiling to filter at once from the hops, as the colour change was rapid if the liquid was allowed to cool on the hops. The colour changes were slow after the hot filtration; in some cases the liquid did not filter quite bright, and they were measured in this condition. The unit value of the black curves represent the different degrees of this turbidity. Attempts were made to re-filter after cooling, but it was found that the necessary exposure brought about other changes, and this procedure was abandoned.

The analysis of the chalk-well water used is as follows:—

	Grms. per Litre.
Total solid matter	0.508
Calcium carbonate	0.202
" nitrate	0.0267
Sodium chloride	0.0343
Magnesium carbonate	0.0071
Silica	0.0076
Sulphates	None.
Phosphates	Trace.
Oxide of iron	Trace.
Free carbonic acid	0.126

Illustration.

The illustrating charts are based on the laws which govern the appreciation of colour by the vision, and have already been before this Society. It will be only necessary to call attention to two of them.

1st. The vision can only simultaneously distinguish two colours in the same beam of light.

2nd. The two colours simultaneously distinguishable are always those adjacent in their spectrum order, red and violet being considered adjacent for this purpose.

Except in two instances of water containing sodium chloride, where green is present, red, orange, and yellow are the only colours in the liquids before us this evening; therefore, apart from these two cases, the only possible combinations are red with orange and yellow with orange; but, of course, in any proportions, the effect of these combinations on beer is pleasing as the yellow preponderates,

and displeasing as the red preponderates; and so far as my own experience goes, delicacy of flavour is associated with yellow preponderance and coarseness of flavour with red preponderance.

In constructing the colour charts, measurements were made at stated intervals of strata thicknesses in accord with the numbers on the horizontal lines. The measured colours were then plotted on perpendiculars through these numbers in accord with the scale of colour units on the perpendiculars of the charts; then by joining the points of similar colours, the specific colour curves for each substance are established.

In the lantern illustrations each line is numbered in accord with a chart number, and the colours are made up with the standard glasses used in obtaining the measurements used in constructing the charts.

The solutions in the bottles are duplicates of the solutions used in constructing the charts, and are numbered in accord with them.

We have before us three methods of demonstrating the nature of the colours produced:—

1st. On the charts, by means of the coloured lines, which indicate the numerical or unit colour depth of each of the

constituting colours which, when combined, produce the colour sensation of any given stratum thickness.

2nd. By transmitting light through the glass combinations used in making the chart measurements, reproducing in each case the colour of the liquid.

3rd. Duplicates of the liquids used in glass bottles of 4 ins. diameter; they are therefore in accord with the 4-in. strata measurements on the charts, and with the colour produced by the glass combinations in the fourth place in the lines on the screen.

For the purpose of bringing these colour curves into some degree of order for comparison, they are divided into three types or divisions, according to the nature of the colour sensations they produce, as represented by the absorption curves.

In No. 1 type the yellow curves preponderate over the orange curves at all densities; this type includes those light-coloured ales known technically as "pale" and "golden-yellow," and probably correspond to Dr. Mierau's terms, "light yellowish fluid," "pale beers," and "much paler." The experiments contain the following instances of this class:—

NO. 1 TYPE.

No.		Strata Thicknesses of Maximum Colour.					
		Yellow Units.	Inches.		Orange Units.	Inches.	
4	Chalk-well water, boiled and filtered	60	at 15	and	16	at 15	
9	Distilled water with 0.2607 grm. magnesium bicarbonate.	83	at 18	and	7	at 18	
13	Distilled water with 0.05 grm. magnesium bicarbonate.	56	at 15	and	17	at 15	
12	Distilled water with 0.10 grm. sodium bicarbonate.	88	at 18	and	17	at 15	
10	Distilled water with 0.15 grm. sodium chloride.	68	at 15	and	7	at 7	{ Orange disappears at 12.5 in favour of green. { Orange disappears at 13.5 in favour of green.
11	Distilled water with 0.3 grm. sodium chloride.	84	at 15	and	13	at 11	

In No. 2 type the yellow preponderates over the orange at the lower densities then decreases, in favour of orange at the higher densities; this type includes those ales known technically as "deep golden," and probably corresponds to Dr. Mierau's term "much yellower colour."

NO. 2 TYPE.

No.		Strata Thicknesses of Maximum Colour.			
		Yellow Units.	Inches.	Orange Units.	Inches.
1	Distilled water	48	at 14	44	at 18
3	Chalk - well water, boiled, not filtered.	49	at 13	76	at 18
8	Distilled water with 0.1307 grm. magnesium bicarbonate.	56	at 2	72	at 18
14	Distilled water with 1.0 grm. sodium bicarbonate.	18	at 8	86	at 18

In the paler examples of this type, yellow preponderates over orange at the lower densities, and red at the higher densities. In the medium examples, yellow is less than orange at all densities. In the extreme examples, orange preponderates over red at the lower densities, and red preponderates in the higher densities. A distinguishing feature in the members of this type is, that red is always one of the two distinguishing colours at the higher densities. All high-coloured ales will be comprised in this group which probably corresponds to Dr. Mierau's term, "strongly coloured fluid with a specific reddish tint."

It would be unsafe to draw conclusions from a few preliminary experiments such as these, but it may be permitted to draw attention to some of the most characteristic agreements and differences, such as that already mentioned as existing between a calcium bicarbonate water before and after boiling. A reference to Nos. 2 and 4 diagrams will show that the effect of removing the calcium bicarbonate from a chalk-well water by boiling and filtering is to convert it from a water which produces a dark-coloured extract, classable into No. 3, the worst type of colour for ales, into a water producing a light-coloured extract, classable into No. 1, the best type of colour for ales.

NO. 3. TYPE.

No.		Strata Thicknesses of Maximum Colour.					
		Yellow Units.	Ins.		Red Units.	Ins.	
2	Chalk-well water	66	at 8	disappearing at 13.5	in favour of 56	at 15	
7	Distilled water with 0.06535 grm. magnesium bicarbonate.	15	" 53	"	5.5	" 46	" 15
5	" " " 1.0269 " calcium "	19.8	" 8	"	16.0	" 8	" 18
6	" " " 0.513 " " "	8	" 6	"	9.5	" 76	" 18
		Orange Units.					
18	Chalk-well water with 150 grms. sugar crystals	21	" 4	"	7.5	" 12.5	" 9
17	" " " 100 " " "	43	" 4	"	6.5	" 20.5	" 9
16	" " " 50 " " "	25	" 4	"	6.7	" 38.0	" 9
15	" " " 5 " " "	20	" 4	"	4.0	" 61.0	" 9

No. 1 TYPE.

No. 4.

Chalk-well water boiled 10 mins., then filtered and boiled 10 mins. with 3 grms. of hops.

Colour units.

No. 12.

0.10 gm. sodium bicarbonate per litre distilled water boiled 10 mins. with 3 grms. of hops.

Colour units.

No. 11.

0.3 gm. sodium chloride per litre boiled 30 mins. with 3 grms. of hops.

Colour units.

No. 2 TYPE.

No. 3.

3 grms. hops per litre of chalk-well water previously boiled 10 mins. Not filtered, then boiled 10 mins.

No. 8.

0.1397 gm. magnesium bicarbonate per litre distilled water, with 3 grms. of hops.

No. 1.

3 grms. of hops per litre of distilled water boiled 30 mins.

No. 3 TYPE.

No. 15.

0.59 gm. sugar per litre of chalk-well water boiled with 3 grms. of hops.

No. 6.

0.513 gm. calcium bicarbonate per litre distilled water. Boiled 30 mins. with 3 grms. of hops.

No. 2.

Chalk-well water boiled 30 mins. with 3 grms. of hops.

BLACK
YELLOW
RED
ORANGE
GREEN

A reference to the colour curves of No. 15, 16, 17, and 18 will show that the addition of sugar crystals to a calcium bicarbonate water reduces the colour without altering the type from No. 3; the reduction of colour has some relation to the proportion of sugar used, lessening as the quantity increases.

On comparing the composition of the waters producing the pale solutions in No. 1 type, that containing 0.2607 gm. magnesium bicarbonate may be left out of the question for the present, as this salt, in other proportions, is represented also in No. 2 and No. 3 types, and requires more preliminary investigation. This division also contains one example of sodium bicarbonate and two examples of sodium chloride. The specific colour curves of these sodium salts are somewhat similar in type with those of No. 4 natural chalk-well water from which the calcium bicarbonate has been removed, boiling and filtering. If we compare the same curves with the darker curves of No. 1 distilled water in the second division, an impression is created that the pale colour of the sodium solutions may be due to specific combinations of these salts with some principle in the hops, and not due merely to the absence of calcium bicarbonate.

The colour of No. 1 in the second division is simply that of hops extract in distilled water, and is useful for comparing with variations in colour caused by the salts other waters. The colour of No. 3 shows that natural chalk water with the calcium carbonate in suspension produces a type of curves similar to distilled water, but containing a larger proportion of orange.

Division 3 contains only examples of the most objectionable colours, that is, having red preponderating in the higher densities. It may therefore be assumed that these waters are objectionable for brewing; and as we have deferred the consideration of the magnesium waters for the present, there remains only the natural chalk water No. 2, containing 0.020 gm. calcium bicarbonate per litre, and No. 6 distilled water, containing added calcium bicarbonate. Their specific colour curves tend to confirm the view that calcium bicarbonate is objectionable for brewing. This set of experiments does little more than point to the necessity of more exhaustive work.

DISCUSSION.

The CHAIRMAN, in inviting discussion, said that all must have listened with great pleasure, especially those who were connected with the brewing trade, to the very interesting communication which Mr. Lovibond had made. He had been in the habit of using Mr. Lovibond's tintometer for a long time past, and found it to be decidedly superior to any other instrument used for colour estimation. It not only gave the total colour, but also the proportion of each of the constituent colours in a given liquid, and was especially valuable in the examination of beers and caramels.

Mr. J. HERON was very much pleased to have heard Mr. Lovibond's paper, because it was the first time that a paper of such a nature had been read before the Society in connection with brewing. He would be very sorry to criticise adversely any paper read by Mr. Lovibond, but it struck him that the author had performed a certain amount of experimental work which hardly obtained in practice, because instead of adding the hops to malt wort and experimenting upon such a solution, Mr. Lovibond had made an infusion of hops with water having certain mineral constituents in solution. It was shown that the addition of sugar diminished the shade of colour to a large extent, and he would like to ask Mr. Lovibond whether he had made any experiments with malt wort, and what would be the nature of the change when the wort was boiled up with the hops. Of course a certain amount of precipitation took place, and perhaps some bodies which gave a red colour would disappear during the boiling. He himself had made a number of experiments on solvent action of the different salts in brewing waters on hops, not so much with a view of ascertaining the colour as of determining the flavour and quality of the extract. He must congratulate Mr. Lovibond on attacking the question from his point of view, and hoped that the paper just read would be the first of many valuable contributions on the same subject. The application of the

tintometer to brewing operations opened up a very wide field of inquiry; there were questions of very great importance in connection therewith which might be attacked in that way, so that brewers would probably be able to tell, not only whether the hops had been properly kilned, but could gauge the quality of malts by the nature of the colour curve.

Mr. E. GRANT HOOPER would have liked to have heard a little more with reference to some other features accompanying the question of colour, and more especially as to flavour. He knew that it was extremely difficult to express or describe a flavour, but when he saw the samples placed before the meeting he could not but think the difference of colour represented to some extent also a difference of flavour. From a brewing point of view the flavour was of the greatest importance, though of course regard must also be had to colour. From an inspection of the diagrams, it seemed to him that the introduction of sugar, which Mr. Lovibond had that evening said very little about, made a great difference to the colour, as indicated by the red line on the third series of plotted curves before the meeting. He rather thought, too, that the precipitation of solid matter in the solutions had more to do with the colour than Mr. Lovibond had suggested. In the two charts of type 1, Mr. Lovibond showed a chalk-well water which had been boiled 10 minutes and another which had been boiled 30 minutes. On the first chart was shown a black line which indicated opacity, and in the second there was a total absence of the black line, but the yellow line went up pretty straight and apparently equal in both of them. Yet he could not but think that the precipitation which had occurred had at least affected the colour to some extent, since it was a common experience that a substance precipitated in an organic solution left the liquid of lighter tint, and he was of opinion that the use of a hard water had a greater influence upon the colour of wort than appeared from the abstract of the paper which Mr. Lovibond had presented to them that evening. It was certainly a feature which possibly had not been much thought of before, that the colour of beer was derived partly from the hops, and was not exclusively due to the malt. It would, however, probably be more interesting to study the effect of different waters upon malt products, because the degree or difference of colour due to these bodies was certainly more varied and more decided than could be due to hops. He had been interested in hearing from the Chairman that he had found the tintometer of such great use.

Mr. LOVIBOND said, in reply, that the paper was only one of preliminary investigation. A beginning had to be made somewhere, and he had begun with hop samples because his attention had been drawn in that direction by a paper by Dr. Mierau. He had no reason to suppose that his experiments would not apply to malt also. The colour curves illustrated were specific for the substances themselves. Malt in common with other substances had a specific rate of absorption, varying probably with the quality of the malt; he knew that it was so with caramels and roasted malts, and on referring to the lines shown, say on charts Nos. 1 and 2, it was a fair inference that the particular lines indicated substances formed by hops under the conditions named; and in that way the method became an analytical one for the discovery of compounds which had hitherto escaped detection. The presence of solid matter had only the effect of darkening the colour; it did not alter the nature of the curves; it simply made it impossible to carry the investigations so far if solid matter were not present. The specific nature of the chemical compound represented by the colour curves would be unaltered, but the power of seeing them would be reduced by the opacity of the mixture. In reference to colour and flavour, he was quite sure that each colour had a co-related flavour. He said 25 years ago, at the time when his attention was called to the objectionable flavour produced by using an unboiled chalk-well water, he did not then appreciate the colour differences which probably accompanied the changes in question. The inference to be drawn was that the colour of the beer was reduced by boiling the water, and was co-related to a fine flavour, as compared with a coarse flavour produced by the unboiled water. It was impossible to

imitate a specific pale colour. Caramel might be added, but the colour could not be imitated; although it might approximate at one density, it would diverge as the density increased; and if a beer was submitted to him in which a pale malt colour had been imitated by caramel, it could be detected by its yielding the colour curves specific for caramel. Sugar, so far as he could judge, only modified the effect of calcium bicarbonate on beer. He had used in the series referred to a chalk water unboiled, with four proportions of sugar. What the effect would be with malt wort was a question open to investigation. His own interest had been very much quickened by the present experiments, as the results obtained were unexpected — alkalis, for instance, showing a pale colour with distinctive curves at the low strengths, whereas he had previously thought that alkalis would probably give a dark extractive colour, but he found instead these distinctive light colour curves. In chart No. 14 the alkali was increased to one gramme per litre, and instantly there was a change into a more degraded class, indicating that, at that strength, the usual alkaline action on organic matter had commenced.

Mr. HOOPER said he gathered that the presence of a precipitate in a liquid in no way affected the colour. He thought that those who had had experience of analytical work would agree that where a precipitate had been produced the colour was lightened. Did it not follow that the elements of the colour had really changed by the removal of one or more of the colour-producing substances?

Mr. LOVINSON thought that reasoning would apply if the solid matter itself was coloured, but if colourless it would not affect the curves, but would simply render the colour more obscure. It was in fact just the difference between a definite chemical compound and a mechanical mixture which gave the mean of the bodies mixed.

Mr. HOOPER understood that the precipitate carried down the colouring matter with it.

Mr. LOVINSON: Unless you have made experimental measurements which prove that, I do not see how you can arrive at such a conclusion, knowing as I do how difficult it is for the unaided vision to judge in such cases within certain limits whether the visual differences are caused by intrinsic colour changes or by variations in the quantity of light transmitted.

Mr. J. C. RICHARDSON: But the matter suspended in a stable compound would not affect the absorption number of that compound if it did not disturb the molecule.

Mr. LOVINSON: That is my view exactly.

Meeting held Monday, February 3rd, 1896.

MR. B. E. R. NEWLANDS IN THE CHAIR.

THE MANUFACTURE OF LINOLEUM.

BY WALTER F. REID, F.I.C., F.C.S.

THE linoleum industry is a comparatively modern one, the first factory having been established about 30 years ago. Like so many products, however, of modern science, linoleum had numerous precursors, through which its evolution may be traced from a very remote antiquity. The first stage in this evolution was waxed cloth or canvas, and to this day oil-cloth is called "Wachstuch" in Germany and "toile cirée" in France. In this country the term "cerc-cloth" does not seem to have been applied to the newer material, partly perhaps because the chief use of cerc-cloth was for the preservation of dead bodies, but also, I think, because the manufacture of oil-cloth originated in this country, and with it the new word. It is generally stated that the brothers Van Eyck first introduced the use of oil in painting towards the middle of the 15th century; but this statement is certainly incorrect. A varnish called "lineleon," containing linseed oil, was used in the 8th century. In 1239, in the reign of Henry III., oil was used for painting in this country, and the account-rolls of our kings since that time make frequent mention of painter's oil, which, at the end of the 13th century, was worth 1s. a

gallon in England. In Italy, also, boiled linseed oil was in common use among painters at the end of the 14th century, for Cennini gives clear instructions for the preparation of "Polo bollito con fuoco," as he quaintly calls it. In Germany the use of oil in painting seems also to have been well known in the latter half of the 14th century, for Theophilus and Erasmus allude to it in very clear terms. A foreigner travelling in England in the 15th century gives an interesting account of the way in which our artists then worked. The canvas was laid upon the floor, and the colours applied to it in this position. He states, as something noteworthy, that these English artists kept their feet clean. Perhaps it is to this habit of keeping the feet clean that we owe the first use of oil-cloth as a floor covering. However, the first use to which oil-cloth seems to have been put was for hangings or tapestry and for windows. In 1636 a patent was granted for "painting with oyle cullors upon wollen cloath, kerseys, and stuffes, being pper for hanging, and alsoe with the said cullors upon silk for windowes." Numerous mixtures of oils with resins of various kinds were used until 1751, when we have the first notice of the use of "india-rubber or gum lastie" as an ingredient in the coating material. This brings us a step farther towards linoleum, for, after various compounds of india-rubber had been suggested, E. Galloway, in 1841, proposed the addition of pulverised cork to plastic india-rubber in order to give a "certain elasticity" to the combination. This compound laid upon canvas was proposed as a substitute for floor-cloth, and is practically what was known a few years later as kamptulicon. The machinery and methods adopted in the production of kamptulicon much facilitated the development of its successor; indeed, some of the improvements suggested for kamptulicon have only lately been applied to linoleum. For instance, in 1851, L. S. L. Bunn made kamptulicon upon wire gauze instead of canvas, and he also invented a method for producing mosaic patterns. At first the inventor of linoleum, F. Walton, called his new product kamptulicon, and it was not until several years after its invention that linoleum became known under its new name. The cement was patented in 1860, and, after supplementary patents had been taken out in 1861 and 1863, the Linoleum Manufacturing Company was founded in 1864. After the lapse of the original patents other factories were founded, and there are now 25 factories in which linoleum is produced, the greater number of which are in Great Britain.

The two chief ingredients in the manufacture of linoleum are cork and linseed oil. To these are added smaller quantities of kauri gum, resin, and pigments of various kinds. Formerly the bulk of the cork used came from Spain and Portugal, but large and increasing quantities of that material are now produced by Algeria, where there are very extensive forests of the cork oak. In the manufacture of bottle corks about one-half of the cork is wasted, and this waste is the main source of supply for the cork used in linoleum works. There is, however, a very large quantity of cork available in the forests, which, though not suitable for the manufacture of bottle corks, would be of excellent quality for linoleum.

The first operation to which the cork waste is subjected is that of passing it over a deep sieve to which a rapid reciprocating motion is given. The dust and much of the dirt fall through the sieve, while stones, pieces of metal, &c., remain upon the sieve, and are removed from time to time. The lighter cork passes over the top of the sieve to the cork-breaker or crusher. The peculiar characteristics of cork render it a very difficult material to pulverise, and many machines have been devised for that purpose. On the one hand it is elastic, and cannot be subdivided by mere pressure, while on the other it soon abrades the hardest steel. Knives used in cutting cork require sharpening after every two or three cuts. The cork-breaker which appears to give the best results on the large scale, consists of a number of very strong circular saws rotating close to a number of steel bars, the ends of which are toothed in an opposite direction to the teeth on the circular saws. The pieces of cork are pushed along the surface of the steel bars, caught by the revolving saws, and finally torn to pieces

between the two sets of teeth. The teeth require frequent sharpening; but this can be done without difficulty by means of an emery wheel, and, on the whole, this form of machine is one in which the working parts can be easily kept in an efficient state. The cork, after leaving the breaker, is in pieces about the size of a pea, which are passed on to the grinding mills. These are ordinary horizontal mills similar to those used in flour-mills; but the stones should be either lava, sandstone, or some similar rough stone. The French burrs, so indispensable in cement factories, for instance, are of little use for cork, which slips upon their comparatively smooth faces, thus causing the output to be much smaller than in the case of softer but rougher stones. The pulverised cork is next sifted and weighed into sacks, which are placed in a drying stove for about 24 hours. The coarser particles are returned to the mill and re-ground. The powdered cork is an extremely light powder; it is easily suspended in the air, and such a mixture is highly explosive. Great care must be taken to protect all artificial lights about cork mills or mixing machinery, and even with the greatest precautions small explosions are sometimes caused by sparks from the machinery. Speaking after considerable experience of both materials, I would rather handle dynamite in bulk than ground cork in a loose state. Although, as you will see from the sample shown, the ground cork is extremely light and elastic, yet this is one department of the industry we are considering which is capable of considerable improvement. You will all have noticed in cork that a number of dark particles are interspersed throughout the elastic substance of which it mainly consists. These are hard and devoid of elasticity, and, for our purpose, are a deleterious adulterant of the cork. They consist largely of tannin, and, on an average, constitute as much as 10 per cent. of the weight of the cork. By separating these impurities from the powdered cork, a considerable improvement would be effected in the colour and elasticity of the linoleum. It is these portions of the cork that first decay, and if you examine a cork which has been buried in the earth for some time you will find the dark nodules have become cavities, while the surrounding elastic material is comparatively sound. For light-coloured linoleums a simple process for bleaching cork is a desideratum. Many attempts have been made in this direction; but the colouring matter is difficult to destroy without at the same time diminishing the strength and elasticity of the cork. Numerous substitutes for cork have been tried in the manufacture of linoleum, such as sawdust, spent tan, peat, &c.; but the resulting product possesses less elasticity than when cork is used, and consequently wears out more rapidly.

In order to form linoleum the pulverised cork is mixed with a material technically known as "cement," of which oxidised linseed oil is the main constituent. The linseed oil should be of good quality; some varieties oxidise badly and give much trouble in the seasoning of the linoleum. I am not aware of any analytical test that will indicate accurately the drying properties of a given sample of linseed oil. The test usually employed is to heat a portion of the oil to about 500° F., stirring continually, and blowing air through the hot oil. Dense fumes are given off, and, after a time, the oil becomes thicker, and a sample of it, when cooled, should be "stringy," i.e., capable of being drawn out into threads. Oil solidified in this way forms the basis of the cement used in some kinds of floor-cloth—for instance, corticine. It makes a good, tough cement; but the chief objection to its use is the smell, which it retains persistently, and which is, as you will notice, not agreeable. The chemical changes which take place during the thickening of oil by heat are quite different from those which bring about solidification at the ordinary temperature. In the former case there is a loss of weight of about 5 per cent., while in the latter an increase of weight of about 11 per cent. results. There is still considerable uncertainty as to the chemical changes which take place during the oxidation or "drying" of linseed and similar drying oils. Although Mulder has thrown much light upon the chemistry of the subject, subsequent observers have not been able to confirm his results in several important

particulars. Hazura, for instance, to whom we owe some valuable researches on the subject, found 5 per cent. of glycerin in linoxyn. This shows that the substance formerly called linoxyn is a glyceride—a fact which Mulder failed to detect. Hazura regards the drying oils as mixtures of linolenic, isolinolenic, linolic, and oleic acids, all of which are liquid. These liquid acids were isolated from various oils and the proportions of the various constituents were found to be as follows:—

	Per Cent. of Liquid Acids.				
	Linseed Oil.	Hemp Oil.	Nut Oil.	Poppy Oil.	Cotton Oil.
Linolenic acid	15	15	13	5	..
Isolinolenic "	65	70	7	30	40
Oleic "	15	15	80	65	60
Linolic "	5	70			

The oleic acid plays no part in the drying process; but the glycerides of this and the other fatty acids are said to be split up into the free fatty acids and glycerin, the latter being oxidised to carbonic acid and water. Water is undoubtedly produced in considerable quantities during the oxidation of linseed oil; but it is probable that acrolein is one of the chief products of the decomposition of the glycerin, as it is evolved in considerable quantities. The glycerides of the drying acids are supposed to be converted into glycerides of the corresponding oxy-acids. Hazura states that the end product of the drying is the solid oxylinolein. Had he extended his researches over a longer period he would have found that this solid is still further oxidised into a semi-liquid body, of which you see here a sample, and to which I called attention on a previous occasion (this Journal, Nov. 30th, 1894).

Apparently this liquefaction has been brought about by means of hydrogen peroxide, for, in 1876, S. Cohné proposed to convert drying into lubricating oils by means of this reagent. Ozone considerably facilitates the oxidation of drying oils; but I am not aware that it has been used upon an industrial scale.

The addition of some salts of lead or of metallic lead not only hastens drying, but also increases the total amount of oxygen absorbed. With the addition of finely divided metallic lead, linseed oil will increase in weight by about 14 per cent. in a few days, while without lead the increase is only 11 per cent. after many months. One theory attributes the drying of linseed oil to the growth of an organism named by D. J. Freire *microclados oleorum*. This must be a remarkable organism, not only indifferent to light or darkness, but revelling in such mineral poisons as lead and mercury salts, and actually luxuriating in temperatures far above the boiling point of water.

During oxidation the specific gravity of linseed oil increases considerably. While that of the raw oil is about 0.93 and of boiled oil 0.94, the oxidised material is heavier than water. A rise of temperature takes place, especially during the earlier stages of the operation.

The linseed oil, if freshly prepared, is allowed to settle in tanks before use. Impurities, known under the general name of "mucilage," subside, and, after their separation, the oil is of a better colour when boiled. Water is not altogether insoluble in linseed oil, and there are few oils that do not contain a small percentage of it. It gives rise to much frothing at the commencement of the boiling operation, but may be easily removed by running the oil through a filter of dry salt. The process of boiling the oil does not differ materially from that in general use in the manufacture of paints and varnishes. The temperature is from 300° to 350° F., and should be carefully watched, as overheating would not only deteriorate the oil, but possibly cause an explosion. Linseed oil being a bad conductor of heat, the contents of the pans should be continuously stirred. As soon as the oil is hot, driers are added in the proportion of from 1 to 2 per cent. of the weight of the oil. In some works red lead alone is used; in others, litharge; but a mixture of both these oxides of lead in various proportions seems to be most in favour. In

spite of the researches of many patient investigators, the exact chemical changes which take place during the boiling of linseed oil are still unknown.

The boiled oil is run or pumped from the boiling pans into settling tanks, where a further quantity of "mucilage" is deposited. These tanks, as well as the boiling pans, should be covered in, and provision must be made for the destruction of the fumes given off, which are decidedly offensive. With the progress of synthetical chemistry a use may be found for these fumes; they contain much acrolein and several volatile acids, chiefly of the fatty series. Various methods have been suggested for the oxidation of the boiled oil, but Walton's original process is still used in the majority of factories.

In this process the oil is pumped to the top of a high building and allowed to flow down over a number of pieces of a light cotton fabric known as "serim," which hang vertically from iron bars. The air in the building is heated to about 100° F., and in the course of 24 hours the layer of oil which adheres to the surface of the "serim" solidifies. The flooding with oil takes place daily, and in this way a succession of layers of oxidised oil is deposited on the "serim." The thick sheet of oxidised oil thus formed is now known as a "skin." This method of oxidising oil is slow, and necessitates a considerable stock of oil. The length of a "skin" being about 25 feet, it is evident that however carefully the building may be heated, the upper portion will be better oxidised than the lower. The quantity of oil remaining on the lower part is also greater, and the consequence is that the lower end of a "skin" is invariably thicker and softer than the upper. On the other hand, each layer of oil, once oxidised, is protected from further oxidation by the succeeding layers. In this way the formation of the viscous semi-fluid substance due to the final oxidation of the oil is avoided. In six to eight weeks the successive oxidised layers upon the serim will amount to about half an inch. The "skins" are then cut down and ground between rollers preparatory to the next process. The serim is now quite rotten, and has become a useless and costly adulterant of the linoleum. Many suggestions have been made for expediting the oxidation of linseed oil. Long before the invention of linoleum, in 1851, Froggart passed oxygen gas through the oil for that purpose, and in 1862 Glass proposed heating the oil and then passing air or oxygen gas through it. Walton himself has devised several other methods of carrying out this important operation, but the one I have described is that in most general use.

Of the numerous processes for oxidising oil in bulk, that of Messrs. Bedford appears to be the only one which has stood the test of practice, it being now in use in several linoleum works. The linseed oil is taken in the raw state and is introduced into a horizontal steam-jacketed cylinder inside which is a central shaft which is furnished with arms and can be rotated at a high velocity. The oil only half fills the cylinder, and by the action of the arms or beaters it is converted into spray. The requisite temperature having been attained, which differs according to the quality of oil to be produced, a current of air is passed through the spray. The temperature rises as oxidation proceeds, and is controlled by introducing cold water into the jacket instead of steam. In five or six hours oil can be oxidised in this apparatus; but if required of a light colour a lower temperature is maintained and the process then takes 24 hours.

The defect of most of these rapid processes seems to be that the oil which is first oxidised remains exposed to the further action of the oxidising agent, and becomes over-oxidised before the whole of the oil has solidified.

By whatever process the oil has been oxidised, the next stage—the preparation of the linoleum cement—differs but little in the various factories. The ground oil is mixed with resin and kauri gum in various proportions. A good elastic cement is composed of about 8½ cwt. of oxidised oil, 1 cwt. of resin, and 1 cwt. of kauri gum. The kauri is first pulverised, but the resin, which acts as a flux, can be used in lumps. The mixing operation is carried out in a steam-jacketed pan provided with stirrers, and samples are taken from time to time, it being of the utmost importance that no overheating shall take place. When perfectly homo-

geneous, the cement is run into pans of a convenient size for further treatment. In summer it may be necessary to cool the cement as it issues from the pan in a plastic state, as this material, as well as the ground oil, has a great tendency to heat and even to catch fire if left in bulk exposed to the air. The cakes of cement, before mixing with the ground cork, are cut into smaller pieces and are then passed through steam-heated mixing rolls, with slightly more than their own weight of cork. The rough mixture is then further amalgamated in a mixing drum, various colouring matters being at the same time added according to the colour desired for the finished linoleum. From the mixing drum the material passes into another apparatus resembling a large sausage machine, but of very strong construction. It is called a "German," not because it was made in Germany, but because the mass of linoleum issuing from it bears a strong resemblance to a German sausage. To start this machine steam-heating is necessary, but once at work the heat generated by friction and by the oxidation of the oil is sufficient to soften the mixture. In summer it may even be necessary to circulate cold water in the jacket instead of steam. This machine is undoubtedly an imperfect one. The power which it requires is enormous, and there can be no doubt that much of this power is consumed in mixing over and over again material that has already been sufficiently mixed for the object in view. On leaving the "German," the linoleum material, now in the form of lumps or pellets, is passed through mixing-rolls, in which it is converted into sheets resembling in colour the surface of the finished linoleum. By revolving one of the rolls at a greater speed than the other, or keeping one of them cooler, the mass may be made to adhere to one of the rolls, from which it is removed by a scraper.

In some works the linoleum mixture is rolled on to canvas in the condition in which it leaves the mixing-rolls, but it is sometimes passed through another machine called a "scratcher." This consists of a pair of mixing-rolls similar to the preceding, but instead of removing the coating of linoleum material from the roll to which it adheres, by means of a scraper, a rapidly revolving spiked roller is used, which tears it off in small pellets. This final machine does not appear to secure any greater uniformity in the finished linoleum; on the contrary, pellets of darker colour than the bulk are sometimes accumulated on the spikes of the scratcher, from which they become detached from time to time, and give a spotted appearance to the linoleum, especially in damp weather. The material as it leaves the scratcher has a consistence resembling that of damp earth. It can be balled together in the hand; but, unless subjected at the same time to heat and considerable pressure, it will not permanently retain the shape given to it. The next process is the rolling of the material upon the canvas which forms the backing. This canvas is of jute, and usually 78 inches in width, which allows 3 inches on each side for waste. The rollers are steam-heated, and both revolve at the same speed.

Wire gauze has been suggested as a substitute for canvas, and I have here a sample made under Hembry's patent. The fabric is tough, and of course the iron wire is not so liable to decay as the jute canvas. Owing, however, to the smoothness of the wire, it is difficult to weave gauze of this kind more than 3 feet wide. A fabric in which the wire gauze is imbedded in india-rubber is now being much used, especially for covering stairs.

The linoleum composition is placed in a hopper, from which it falls upon a carrier of wire-gauze which passes through a steam-chest and drops the linoleum between the rolls. The canvas is passed over one of the rolls and under the other, and carries with it as much of the facing mixture as the space between the rolls will allow. This space is adjustable according to the thickness of linoleum required. Under the combined heat and pressure the linoleum adheres firmly to the canvas, and linoleum floor-cloth is the result. Sometimes the fabric is passed between cold polished rolls while still warm, this having the effect of giving a better finish to the surface. In order to protect the canvas back, a species of varnish known as "backing" is spread upon it by means of a machine resembling that used for a similar purpose in india-rubber

and other works. The composition of the "backing" is different in almost every work; but the main ingredients are oxidised oil, kauri, resin, shellac, and colouring matter. The solvents are coal-tar naphtha and methylated spirit, and the consistence should be such that, while fluid in a steam-heated pan, it solidifies sufficiently on cooling to enable the linoleum to be handled. After backing, the linoleum is seasoned in buildings kept as nearly as possible at a uniform temperature of 75° F. It is usually suspended in "bights" from battens, and when this system is adopted, care must be taken to reverse the top and bottom of each bight from time to time, otherwise the upper part, being in the hottest part of the building, would season more than the lower. A better plan is to season the linoleum in horizontal racks, in which each piece, being at one and the same level, has a better chance of seasoning uniformly.

Linoleum made as described is of one colour throughout, and when an ornamented surface is required this is supplied by means of designs printed upon it in oil-paint in the same way as is done with its predecessor, oil-cloth. This oil-paint, however, soon wears off, and, as we have seen, even in the pre-linoleum, kamptulicon times, efforts were made to produce coloured patterns extending right through the thickness of the coating composition. The simplest way of doing this is obviously to roll simultaneously and continuously mixtures of different colours upon the same canvas side by side. This produces stripes of different colours, and although the effect is not adapted for large surfaces, yet for passages or stairs this cheap method may be of some utility. The first practical step in this direction was, I believe, taken in 1885, and in 1891 and 1892 T. Mitchell devised a process by which the samples before you were produced. A partitioned frame is fixed opposite the rolls in such a manner that the linoleum material is drawn between the rolls by the backing canvas. Each partition in the frame contains linoleum of a different colour, and the stripes are subsequently welded together by the pressure of the rolls. Provision is made for the adjustment of the width of each partition and consequently the breadth of each stripe.

But modern requirements for the ornamentation of surfaces necessitate something more than stripes, and several methods have been developed to produce patterns of the most varied character extending right through the bulk of the coating layer of the linoleum. Time will not allow of a description of all these methods, and I shall therefore select those which have been carried out on the most extensive scale. Two main principles have been chiefly successful: one is the use of stencils or grids to mould or shape the loose material into designs, and the other is to use cutters or knives which cut out pieces of the material that has already been partially compressed into a sheet. Of the former kind are the machines of Godfrey, Leake, and Lucas. In the first instance most of the operations comprised in this process were carried out by hand, but the inventors have lately devised a machine to perform the whole of the work automatically. The cloth or canvas, which may already bear a thin facing coat of linoleum material, is carried along the surface of a horizontal table. Stencil-plates, with openings corresponding with the different parts of the design to be produced, are lowered upon the cloth, and a measured quantity of granulated linoleum is distributed upon each stencil-plate and passed through the openings by means of scrapers. The plates, which travel about their own width on and with the moving canvas, are then raised again and returned to the first position. The canvas bearing the granulated linoleum then passes through heated rolls, between which it is consolidated in the usual way. Another method adopted by the same inventors for producing a mosaic pattern, is to spread the granulated linoleum material upon a table and then to lower upon it a grid, the divisions of which are of the shape of the tesserae. Plungers or dies are then inserted into the divisions corresponding with the colour of the linoleum upon the table. On lifting the grid only those divisions will remain full in which the material has been consolidated by the dies. The process is repeated with different colours, and the tesserae are then discharged upon the backing fabric, the whole being subsequently

consolidated in a press. When narrow outlines are required between the tesserae forming the bulk of the design, a stencil of wire netting is used, bearing, affixed to its lower surface, metal plates corresponding in shape with the tesserae which are already upon the canvas. Granulated linoleum is then brushed through the netting and fills up the outline spaces. The stencil is then removed and the whole surface consolidated by pressure. What is known as inlaid linoleum is made under the patent of C. F. Leake, the carpet inlaid being the joint invention of Leake, Godfrey, and Lucas.

A different principle is adopted by F. Walton, who employs cylinders fitted with cutting knives shaped and arranged according to the pattern. Between these knives are radial pistons or plungers, which push out the pieces cut from a sheet of linoleum material and fix them upon a cylinder covered with projecting pins. Between the pin cylinder and the tesserae the backing canvas is stretched, and when the whole of the pieces forming the pattern are cut out, the canvas leaves the pin cylinder, carrying with it the tesserae which are then subjected to pressure sufficient to cause them to adhere to each other and to the backing. Instead of cutting out the tesserae from a previously rolled sheet, the same inventor has devised a machine in which the tesserae are moulded as required. Granulated linoleum material is placed in a hopper fixed above a cylinder furnished with recesses, each of which is of the shape of the tesserae to be produced. The bottom of each of these recesses is movable and furnished with pins which project into the interior of the hollow cylinder. Inside the moulding cylinder is another cylinder which is eccentric to it, and as the former revolves the latter presses upon the pins, pushing the bottom of the die outwards and gradually ejecting the tesserae formed. These tesserae are delivered on to a travelling band or carrier, furnished with needle-points, which retain them in their proper positions and carry them along a horizontal table. There they are fixed upon the canvas, which is to form the backing of the linoleum, by pressure between other rolls. Apart from the difficulty of securing an accurate register by this means, the machinery is complicated, requiring 28 rolls for a four-colour pattern.

Although these inlaid linoleums have some advantages as compared with those which preceded them, yet they have also disadvantages peculiar to themselves. In order to secure colours of sufficient brilliancy the linoleum must be mixed with considerable quantities of colouring matter. These pigments are of different chemical composition; therefore a variegated piece of linoleum cannot be regarded as a homogeneous sheet. In course of time the texture of the various tesserae varies according to the chemical changes taking place in each. In the case of linoleums built up of tesserae cut from previously rolled sheets, the cohesion at the junction lines of the different colours is much less than in a sheet of one colour, or even in a sheet composed of various colours which have been consolidated in the granular form. The elasticity of these linoleums is much less than that of the plain material, partly because of the pigments used, and partly because increased pressure is required to ensure thorough cohesion between the tesserae.

Printing linoleum is a simple operation, similar to printing wall-papers and oil-cloth by hand. But, in order to ensure success, special precautions have to be taken. The blocks are made of wood, into which strips of brass are inserted, the edges of these strips forming the printing surface. Where a considerable surface has to be printed the block must not be solid; but the field must be built up, as it were, of a number of parallel lines somewhat like the shading in a woodcut. There must be a block for each colour, and, in addition, a "smash" block is used for patterns which contain large surfaces of colour. The Addlestone Linoleum Company, Limited, have kindly prepared these samples, which will, I hope, convey a good impression of the successive operations of linoleum printing. Although the pattern is a simple tile one, consisting of alternate black and white squares, yet five blocks have been used to produce it. Upon the piece marked 1 the white body colour alone has been printed. To No. 2 the black body has been added. No. 3 has had the black tiles more

clearly defined by the black outline block, and in No. 4 the same operation has been performed with the white. In No. 5 the "smash" block has been used, which, you will notice, has considerably smoothed the surfaces of colour. Sometimes the outline blocks are used before the body blocks; much depends upon the quality of the blocks themselves, as well as upon the character of the design. By working the natural colour of the linoleum into the design, it is obvious that a third colour could be obtained with the same number of blocks. Oil colours alone are used for linoleum, and I fear more attention is paid to the quick drying of the paint than to its durability under wear. The fact that a considerable thickness of colour must be laid on has prevented the use of cylinder printing machines. A machine has, however, been devised in which printing is done in much the same way as by hand. Blocks covering the whole width of the linoleum are made to rise and fall alternately, first upon a colour pad run in underneath them, then upon the surface of the linoleum, stretched upon a table underneath. The "register" is obtained by fixing the edges of the linoleum upon steel pins carried by an endless steel band at each side of the table. The cost of the blocks renders the use of such a machine remunerative only when large quantities of one pattern have to be printed.

After printing, the linoleum has again to be seasoned until the paint has set. The edges are then trimmed by hand, and the fabric is ready for use. Plain linoleum is usually made in two colours, brown and red. The brown is generally the more elastic, but it has the disadvantage of showing marks more plainly. We live in the iron age, and any article of iron placed upon wet linoleum will leave a dark mark. This is due to the action of the tannin contained in the cork upon the iron. In course of time linoleum becomes hard and brittle; here is a piece about 16 years old, which was originally as supple and elastic as the samples you have just seen. The particles of cork remain quite elastic; it is the cement which has hardened. The oxidised oil in it has become further oxidised, and the resulting acid bodies have combined with the pigments and other constituents, forming inelastic substances. It will be difficult to find a substitute for the cheap and durable cork; but probably a more stable cement will be found, possibly derived from mineral oil. Whatever defects linoleum may possess, it is at the present time undoubtedly the best and cleanest floor covering, and I think an inspection of the numerous patterns before you will convince you that in appearance it leaves nothing to be desired. Our thanks are due to the Staines Linoleum Manufacturing Company and to the Addlestone Linoleum Company for most of the interesting samples which you have seen.

DISCUSSION.

The CHAIRMAN having invited discussion:—

Mr. F. WALTON had listened with great interest to the paper. Mr. Reid's facts were not correct in every particular, but the paper was nevertheless full of valuable information. The growth of the industry had been a matter of great surprise to him. When he made the first piece of what was now called linoleum—but which was not as Mr. Reid had stated then called kamptulicon—it was considered impossible to deal with india-rubber in that way because it was too intractable to adhere to the rollers without injuring the fabric. He had succeeded in realising the use of oxidised linseed oil, and that was the beginning of an industry which had now reached a production of 12,000,000 yards annually. And he believed that the industry was still in its infancy, and that its future lay in the development of the improvements which the author had explained, namely, the production of fabrics with the pattern running right through.

Mr. W. F. REID, in reply, thanked the members for the kind way in which his paper had been received. As Mr. Walton had called his accuracy in question with respect to the naming of linoleum after its predecessor kamptulicon, he would remind him of the paper which he, Mr. Walton, read before the Society of Arts in 1862, when he described his linoleum cement. In that paper, after showing the resemblance of the cement to india-rubber, he said: "Fibre, whether flock or cork, mixed in and rolled into sheets, gave

me samples of kamptulicon and other floorcloths." In the list of applications of the new cement he mentioned "kamptulicon (of any colour)."

Mr. F. WALTON replied that when he read the paper referred to he had no idea of such a fabric as linoleum. He was then connected with a firm of india-rubber manufacturers, and invented a fabric made from oxidised oil and cork for which he suggested the name of kampticon. Later on, he made a similar material rolled on canvas, which was immediately recognised as a valuable invention, and to this was given the name linoleum, the word having been coined by himself in conjunction with an Essex clergyman.

The CHAIRMAN complimented Mr. Reid on having produced a valuable historical record of the linoleum industry, in which he had rightly given honour where it was due—especially to Mr. Walton, the father of the manufacture.

Mr. H. DE MOSENTHAL exhibited some examples of Röntgen's new photographic method, including the bone structure of a frog and of a human hand and wrist seen through the surrounding flesh and skin, and gave a description of the apparatus for producing and using the rays which, for want of a better term, are known as the *x* rays.

Mr. OSCAR GUTTMANN, while not questioning Prof. Röntgen's right in regarding himself as the discoverer of a new kind of light, called attention to the fact that other investigators had observed phenomena and produced results resembling those described and claimed by him. Records of such work had recently appeared in the Proceedings of the Hungarian Society of Civil Engineers. Moreover, Dr. Goldstein, an assistant of Helmholtz, had published, eight or nine years ago, in the German papers, photographs of objects produced by certain rays, the reason of which he could not explain, and had followed these up by other work in the same direction. A more notable instance still was that of Reichenbach, the inventor of creosote, who, about 1848, published a pamphlet on what he called the Od, which consisted of a sort of halo surrounding every natural body, and rendering it luminous under certain conditions. In his writings at that time Reichenbach gave illustrations of bodies which he stated had been photographed through other bodies which were transparent to this illuminating medium or fluid. Du Bois-Reymond had denounced him as a lunatic at the time; but since Röntgen's discovery had excited curiosity in the matter, a certain professor at Cologne had made further experiments, and had actually succeeded in repeating Reichenbach's productions. Last of all, Prof. Edvy-Ilés of Budapest had stepped in and claimed to be able to produce similar photographs to Röntgen's without the aid of either Crookes' or Hittorff's tubes. His method was simply to use a metal plate as the anode, put the sensitive plate on that, then the object to be photographed on that, and lastly, another metal plate as the cathode, connect the plates with the machine, and the picture came out as well as with a tube such as Mr. De Moenthal had described.

Meeting held Friday, January 3rd, 1896.

MR. GEORGE E. DAVIS IN THE CHAIR.

THE EFFECT OF HEAT ON THE ILLUMINATING POWER OF COAL-GAS.—ITS RELATION TO THE THEORY OF FLAME.

BY WILFRID IRWIN.

You may remember in my last paper (this Journal, 1895, 546) that I demonstrated to you the fact, which I believe I was the first to point out, that when used in conjunction with the same gas, different enrichers do not give the same comparative results with different burners. Thus, suppose we take—

Hydrogen + benzene, with union jet,

Hydrogen + pentane, with union jet,

Hydrogen + benzene, with Argand,

Hydrogen + pentane, with Argand,

you readily notice how much greater influence the Argand burner has in increasing the illuminating power of the pentane flame than the benzene flame.

The converse I also showed to be true, namely, that the same enricher with the same burner will yield different results with different gases. Thus, benzene added at the rate of 1 gallon per 10,000 cubic feet of a 15-candle gas composed of disilluminated gas + benzene will give an addition of more than three candles with the Argand burner, whilst with ordinary 15-candle coal-gas a result of barely half that amount would be obtained.

With the object of accounting for these phenomena, I have made the following experiments:—

I. A wrought-iron 1-in. pipe, 4 ft. in length, was placed in a furnace in a horizontal position in such a way that the central portion only was heated. One end was connected with a supply of ordinary Manchester gas, the other by means of an india-rubber tube to a glass vessel, through which the gas had to pass on its way to a burner, the ordinary union jet being the one employed.

A stream of gas was now slowly passed through the pipe, whilst the temperature of the furnace was gradually raised, and a light having been applied to the burner the action on the flame was carefully watched. Up to a dull red heat no alteration whatever in the flame was observable. At a medium red heat the illuminating power of the flame just began to give way, whilst another slight increase caused it to decline rapidly and in fact it soon fell to below 1-candle power. No smoke was to be seen in the glass vessel between the pipe and the burner, nor on looking down the former, whilst the gas was passing, was any luminous glow visible, and only a slight deposit of carbon was formed on the side of the pipe. The temperature at which this change in the gas occurred was determined by Siemens' method, and found to be 830° C. This figure is probably a little below the mark, but I think we may safely say that the temperature at which gas becomes practically non-luminous with the union-jet flame to be somewhere between 850° and 900° C.

The resulting feebly luminous flame plainly shows stratification into five layers. Namely—

1. The lower non-luminous layer.
2. The lower luminous layer.
3. The middle non-luminous layer.
4. The upper luminous layer.
5. The upper non-luminous layer.

On proceeding with our experiment and gradually raising the heat of the furnace, the luminous portion became fainter and fainter and the upper non-luminous layer increased in extent. Fumes of smoke began to be visible in the intervening glass vessel, at the same time the last remnant of the old luminosity disappeared but in its place rays of luminous specks, due to particles of ignited carbon issuing from the jet, gave a certain amount of light to the flame.

Other experiments were made with mixtures of hydrogen and benzene and hydrogen and pentane, with the result that the said mixtures were both found to lose their lumi-

nosity at about the same temperature as ordinary Manchester gas.

I next varied the experiment, and instead of cooling the gas between the heated portion of the pipe and the burner, I had a diminisher screwed on the end of the pipe, fitted the burner into it, and arranged my furnace so that the main part of the heat should ply right on the end of the pipe. By a suitable arrangement the gas flame itself was protected from the fumes and light of the furnace so that the action of heat on the gas could be readily observed.

Just at first, after a light was applied to the gas and the furnace kindled, the flame appeared to increase a little in brilliancy, but it soon again began to fall as in the previous experiment. At a bright red heat the stratification became again apparent and the two bright layers, with the dark line separating them, instead of gradually fading away as in the first experiment, began to draw nearer to the orifice of the burner until at last, at an almost white heat, they came in contact with it and one after another disappeared, the flame being again rendered slightly luminous by the red-hot particles of carbon issuing from the burner.

Before commenting on the foregoing results, I wish to draw your attention to experiments with mixtures of pure hydrogen + acetylene and pure hydrogen + benzene. I have here jets of each of the mixtures and can vary the proportions in each as I please. Notice what takes place when the proportions of acetylene and benzene are so reduced that the two flames are only slightly luminous. In each case you will see that the flame becomes stratified and the five layers previously referred to become apparent.

Conclusions. I.—The fact that the passage of ordinary coal-gas or of a mixture of hydrogen and benzene through a red-hot pipe reduces enormously the illuminating power of the said gases without production of soot, and of only a slight carbon deposit in the heated pipe, shows clearly that a decomposition of benzene into other hydrocarbons takes place, which have not the same ability to form luminous products of decomposition as benzene has. It also explains why the Argand burner shows lower results with a gas rich in benzene than the union-jet burner does. The greater heat of the Argand burner evidently acts in the same manner on part of the benzene in the gas as the red-hot pipe does, thus decomposing it before sufficient oxygen can come in contact with it to produce further decomposition into carbon and hydrogen. It is evident from what I have said that it is only when the temperature of the flame is below 900° C. that benzene can be of much assistance in increasing its illuminating power. This action of heat on benzene, &c. also accounts for the fact that you often cannot get the full initial value of different enrichers when added to a gas at the same time.

II.—In my second experiment, when the burner was placed in the hottest part of the pipe, the increase at first in the illuminating power of the flame was due no doubt to that which gives the Argand burner its superiority with ordinary gas—less heat being lost by radiation, a smaller quantity of hydrocarbons is required for combustion in order to maintain the heat of the flame.

The presence of sparks of incandescent carbon at a temperature of 1,100° C. to 1,400° C. shows that a certain amount of ultimate decomposition is now taking place inside the pipe.

The gradual approach of the various layers in the feebly-luminous flame to the orifice of the burner as the temperature of the gas, issuing from the pipe rises, shows that the position of these layers is chiefly one of temperature, and by determining the temperature of the gas before leaving the pipe the heat of the flame at the points of the various layers could be approximated.

III. Having previously shown that the upper luminous layer in these feebly-luminous flames is due to the presence of Marsh gas, there can be no doubt that this gas is one of the products of decomposition in the hydrogen + benzene and hydrogen + acetylene flames which I have just exhibited.

What the other products of decomposition in the benzene flame are and those which enable it to act as such a high enricher, it is difficult to say.

Manchester gas before and after passing through red-hot pipe.

Benzene + hydrogen gas before and after passing through red-hot pipe.

4

Photographs of flame of ordinary gas issuing from the burner at a very high temperature, No. 4 being the highest.

Free acetylene it cannot be as this substance, when diluted with hydrogen, is far less powerful as an enricher than benzene itself, and it also requires in such a diluted form a far higher temperature for its decomposition (according to Lewes's theory) than it could possibly get in the lower part of the flame.

It may possibly be that immediately on formation acetylene is able to decompose at the same temperature as when pure, *i.e.*, about 800° C. but this has not been proved.

Benzene itself is not an endothermic compound and therefore simple decomposition into carbon and hydrogen would not be likely to produce luminosity as in the case of acetylene. From my experiments with the heated gases, I have come to the conclusion that the intrusion of a certain amount of oxygen is required to split up the benzene molecule, the products of decomposition being Marsh gas, carbonic oxide, and solid carbon, the last raised momentarily when in a nascent state to a high temperature by its approach to the hot mantle, which as Professor Smithells has recently shown, surrounds every flame.

Since a flame produced by burning a mixture of hydrogen and acetylene also exhibits stratification it is clear that the question of the cause of luminosity cannot admit of the simple solution put forward by Prof. Lewes; here, as in the other cases, luminosity is produced by two different reactions occurring at different levels and different temperatures and much more labour will be required before any clear light on the subject is obtained.

The whole question of flame luminosity is very involved but if the solid carbon theory be the true one, why do not the particles of solid carbon issuing along with the gas from the highly heated pipe yield an illuminating effect equal to, or even greater than, that of the gas when burnt in the usual manner?

Leaving matters of purely scientific consideration let us consider what light, commercially speaking, can be gathered from the experiments I have described.

The temperature at which I have shown ordinary gas loses most of its luminosity is less than that of all gas retorts towards the end of the process of carbonisation. When a retort is first charged it is absolutely necessary to keep the furnace at a very high temperature in order to obtain the best result of gas. Towards the end of the process, however, this is not the case as less heat is lost by evolution of gas, and may not the low quality of the gas then produced be largely caused by the over-heating of the slow current generated at the time.

It has been suggested by White to pass water-gas through the retort as the charge is nearing the finish in order to reduce the temperature. I am unaware of this having been worked successfully on a commercial scale but there is no doubt that water-gas so treated would require less oil-enrichment to bring it up to a given standard of luminosity.

Before concluding I would like to refer to another point bearing upon this matter and that is the question of the standard burner. When coal-gas only was manufactured, this was not so important, but now that oil-gas, &c. have entered the field and comparisons have to be made, surely some more logical standard than the Argand burner (which, as I have previously shown, is much more sensitive to one enricher than to another) could be adopted. We have superceded candles at one end of the bar of our photometer, surely it is far more important to have a truer standard burner at the other end.

Advocates of other systems of lighting are not slow in finding out the defects in our present method of testing, and are inclined rather to overstate the differences than otherwise, and for the sake of consumers it is very important that a satisfactory settlement of the question should be arrived at.

Meeting held Friday, February 7th, 1896.

MR. GEORGE E. DAVIS IN THE CHAIR.

PHOTOGRAPHY BY THE "RÖNTGEN" RAYS.

BY GEORGE E. DAVIS.

THE most interesting subject at the present time is the discovery by Röntgen that certain rays which accompany the luminous rays of light, pass through many substances which are perfectly opaque to the ordinary rays, and thereafter reduce the silver salts on a sensitive photographic film in the same manner as the so-called chemical rays do.

Röntgen's demonstration of the correctness of Clerk Maxwell's speculations is only a few weeks old, so that not much is known yet concerning the physical properties of these particular radiations, but several demonstrations have taken place, both in this country and abroad, from which something of their nature may be gathered.

Dr. Speiss, the lecturer at the Urania Institution in Berlin, a few days ago gave a demonstration showing that the new rays (provisionally called the "X" rays) pass through wood, aluminium, and many other solid bodies, such as earthenware and ebonite, while they will not pass through most metals, bones, or glass; and he further warned his audience against premature optimism with regard to the practical employment of Prof. Röntgen's discovery.

At the last meeting of the French Academy of Science, M. Poincaré exhibited a number of photographs which had been taken of objects placed behind opaque bodies, and M. Lebon has made a communication to Prof. Arsoval, who laid it before the Academy, tending to show that these "X" rays are not merely altered light rays, but radiations accompanying the luminous rays of ordinary light.

The practical adaptation of the discovery is progressing day by day. It will be as well, however, to bear in mind Dr. Speiss's advice, as the photographs produced, so far, are not in the ordinary sense of the word photographs, but rather prints in which the object takes the place of the negative, as in the preparation of transparencies for the lantern. Up to the present, there is no known method by which these "X" rays can be focussed so as to form an image on a glass plate in the ordinary camera. At Vienna, Prof. Neusser has shown his students a print of a gallstone in the liver, and another of stone in the bladder, but the account does not say whether the prints were produced from the living organism or from post-mortem preparations. Prof. Mosetig is also credited with having demonstrated with the greatest clearness and precision the injuries caused by a revolver-shot in the hand of a patient, and the position and nature, of a malformation in the foot of another.

Amongst the photographs exhibited by Dr. Speiss was one of very interesting character, showing the hand of a servant of the Urania Institution. This man some years ago ran a piece of glass into his hand, which could not be extracted. The photograph by the "X" rays shows this piece of glass quite distinctly. Recently, at the Camera Club in London, Mr. Campbell Swinton showed some photographs similar to those obtained by Professor Röntgen by the use of Crookes' radiant matter tubes. Mr. Swinton employed a half horse-power electric current, and passing it through an induction coil, he loaded 10 Leyden jars. The discharge from them was passed through a second induction coil, by the secondary system of which a Crookes' tube was excited. He stated that he only succeeded in this way, and had failed with Crookes' tube excited by an ordinary induction coil. He further stated that the visible light of the Crookes' tube does not pass through wood and other similar materials, but that the new effects seem to be due to some other radiation which accompanies the visible light, and has the power of penetrating the wood or like material and affecting the sensitive plate when covered by it. He observed that ebonite, carbon, and most organic matters were transparent to this radiation; and that, on the other hand, all metals, except aluminium and perhaps lead, were opaque to it. Curious to say, clear glass was very opaque, but ground glass was less so.

Evidently a great deal of investigation has yet to be made. At present it is stated from Berlin that these radiations are not refrangible, but this seems doubtful; proper media may yet be found. The lecturer produced a photograph of a living human hand, which had been taken by placing the hand on a camera, at the back of the frame containing a sensitive plate, the Crookes' tubes being placed behind the hand. A leather purse containing three coins had also been photographed in a similar way. The coins and the metal clasp were the only objects portrayed on the plate. Both these plates were developed in the usual manner by photographers. I have here a few of these prints for your inspection, and from them you will be able to judge of the importance of the discovery.

ON THE ESTIMATION OF ORGANIC MATTER BY MEANS OF CHROMIC ACID.

BY JOSEPH BARNES, F.I.C.

IN the analysis of water the amount of oxygen absorbed from permanganic acid is generally viewed as a sort of measure for organic carbon, and Frankland has so far recognised this that he has given factors for calculating the amount of carbon from the number obtained by the so-called "oxygen absorbed" test. The extent of oxidation effected by this process is, however, only a small fraction of what would ensue if all the carbon were oxidised to carbon dioxide, and varies indeed with different kinds of organic matter, so that different factors have to be used for different classes of water: the factor for river water being 2.38, whereas that for deep well water is 5.8.

Now, seeing that this test is so largely used in the examination of polluted waters, sewage, effluents, &c., I have endeavoured to work out a process in which the extent of oxidation would be much greater than that brought about by the usual method, so that the amount of oxygen absorbed might be a more reliable measure for the carbon. Processes in which chromic acid serves as the oxidising agent have been described (Paul Degener, *Zeit. f. anal. Chem.*, Vol. 24, p. 129; C. A. Burgardt, *Man. Lit. and Phil. Soc.*, Dec. 14th, 1886; C. F. Cross and E. J. Bevan, *Chem. News*, Vol. 55, p. 2; L. Legler, *Analyst*, Vol. XII., p. 14; Otto Hehner, *ibid.*, Vol. XII., pp. 25 and 44), and are indeed used, though I believe not very extensively; and attempts have been made to effect by its aid complete conversion of the carbon into carbon dioxide, and thus to estimate it quantitatively by determining either the residual chromic acid or the carbon dioxide evolved.

I have made numerous experiments with chromic acid, but have not succeeded in effecting complete oxidation of carbon; and, indeed, whenever the process was conducted with this end in view, there was either a considerable loss of oxygen or of chlorine in the presence of chlorides, or else the process became one that could not be termed "practical."

I eventually fixed upon the following empirical method as one that could be easily worked, and in which the conditions of experiment could be easily maintained by different workers:—25 c.c. of strong sulphuric acid are mixed with 50 c.c. of the solution of organic matter and 10 c.c. of chromic acid solution added. The mixture is then heated for one hour on the water bath, an excess of a ferrous salt added, and the whole titrated back with permanganate.

In all cases parallel experiments have been made with permanganic acid by a process that I have always been in the habit of using for sewage and sewage effluents. Ratios have been calculated in each case from the numbers obtained by the two methods, and are placed in the last column of the table of experiments. These ratios are of interest, and might, after a large number of tests, become of value in differentiating organic substances. It will be observed that the ratios for glycerol, starch, sugar, and gelatine are very low. Tannic acid, infusion of peat and urine give the highest ratios, and albumen and blood give ratios very similar to those of domestic sewage. The gelatine ratio is higher the more putrid the solution becomes. This is not noticeable in the case of albumen, but, if anything, the tendency is the other way. It seems also remarkable that the oxidisability of these solutions to hot chromic acid does

not increase as they become more putrid. The extent of oxidation by means of the chromic acid method amounts in the cases of the albuminoids gelatine and albumen to about 18 per cent., and that of glycerol, sugar, and starch to from 80 to 95 per cent., of what would be required for the conversion of the whole of the carbon into carbon dioxide. As a measure for carbon it is very evident that this method is superior to the permanganic acid one, for although it does not yield an exact measurement for carbon in carbon compounds, yet, on the other hand, the permanganic acid process almost fails to indicate this element in the cases of starch, sugar, and gelatine.

It will be noticed, in comparing the results yielded by different amounts of the same substance, that the influence of mass is very obvious. In the chromic acid process the figures are as a rule higher the less the proportion of organic matter bears to the chromic acid. With the permanganic acid process this is just the reverse. Whether this is owing to a loss of oxygen induced by peroxide of manganese, or whether oxidation proceeds more rapidly as manganoous sulphate is formed, as in the well-known case of oxalic acid, are questions that I am at present not able to answer.

Solutions used in the Experiments.

Chromic Acid.—6.2 grms. of potassium bichromate are dissolved in water; 50 c.c. of strong sulphuric acid are then added and the whole is made up to one litre. The addition of acid prevents the peculiar behaviour of ordinary bichromate solution in refusing to wet the inside of the glass when the pipette has been used for a short time: a more regular delivery is thus ensured.

Solution of Ferrous Sulphate.—18 grms. of ferrous sulphate crystals are dissolved in a mixture of 100 c.c. strong sulphuric acid and 200 c.c. of water: when cool the solution is made up to $\frac{1}{2}$ litre. 10 c.c. of this solution, when mixed with 10 c.c. of the above chromic acid, should yield a solution containing a little residual ferrous salt. A solution of ferrous sulphate containing so much free acid as here given changes in strength with extreme slowness.

Potassium Permanganate.—A solution containing 4 grms. per litre.

Standard Potassium Permanganate for Titration.—This is prepared so that 1 c.c. contains $\frac{1}{2}$ mgrm. of available oxygen, and may be standardised by the usual methods. It is almost exactly one-half the strength of the foregoing.

Strong Sulphuric Acid.—The best quality of commercial sulphuric acid, free from arsenic, and known as "sulphur vitriol," has been used in these experiments.

Dilute Sulphuric Acid.—1 volume of strong sulphuric acid is mixed with two volumes of distilled water; the hot mixture is then coloured pink with a few drops of permanganate solution and set on one side to cool.

The Chromic Acid Process.

Measure 50 c.c. of the liquid to be tested, or if a smaller amount is taken it is made up to this volume with distilled water. Pour it into a flask of 300 c.c. capacity, add 25 c.c. of strong sulphuric acid by means of a graduated cylindrical measure, and, after shaking, run in 10 c.c. of the chromic acid solution, cover with a watch glass, and place on a boiling water-bath, and let it remain for one hour; remove from the water-bath and set the

flask and contents to cool for two or three minutes in a dish of cold water; add 10 c.c. of the ferrous sulphate solution, pour into $\frac{1}{2}$ litre of cold water, and titrate with the permanganate until the green colour of the liquid changes to grey. A blank experiment is done in precisely the same way and at the same time with 50 c.c. of pure water in place of the solution of organic matter, and the amount of standard permanganate used is deducted from that required in the actual test.

Permanganic Acid Process.

100 c.c. of the liquid to be tested, or a smaller measured quantity made up to this volume with pure water, are placed in a stoppered bottle; 10 c.c. of dilute sulphuric acid are then added, and finally 10 c.c. of permanganate (1 grms. per litre). The bottle is placed in a tank of water at 70° F. and allowed to remain $2\frac{1}{2}$ hours, maintaining the temperature at 70° F. if necessary by the occasional addition of hot water. Now add 10 c.c. of the ferrous sulphate solution, and after the liquid has become quite clear, titrate it with the standard permanganate (1 c.c. = $\frac{1}{2}$ mgrm. O.).

A blank experiment is made at the same time with 100 c.c. of pure water, and the amount of standard permanganate used deducted from that required in the actual test.

MR. F. J. R. CARULLA IN THE CHAIR.

NOTE ON THE IGNITION OF SAWDUST BY NITRIC ACID.

BY L. ARCHBUTT, F.I.C.

AN outbreak of fire caused by nitric acid coming into contact with an easily inflammable packing material, such as hay, is not an unknown occurrence, although there do not appear to be many cases on record. The burning of a railway car in Baden some years ago, suspected to have become ignited in this way, led to some experiments by Prof. Haas, a summary of which may be found in the *Analyst*, Vol. VI. (1881), p. 231. Prof. Haas filled boxes of 12 to 20 litres capacity with variable proportions of hay, straw, tow, and blotting-paper, placed these within larger boxes, and filled the intervening space with hay or tow to act as a non-conducting envelope. He then saturated the hay, &c. in the inner box with nitric acid, pressed it down rather tightly, and put a lid on. When very strong nitric acid was used, red nitrous gas quickly appeared, followed by whitish vapours and then smoke, and on lifting the lid the contents of the box were seen to be red hot, and readily burst into flame if stirred up or gently fanned. With acid of 1.395 sp. gr., the action took place more slowly, and 20 minutes elapsed before the final stage was reached, but the same result was eventually obtained as with the stronger acid.

Further experiments by Prof. Haas are recorded in this Journal, Vol. IV., (1885) p. 496. In these, weaker nitric acid was employed, and it was found possible to ignite hay contained in a box by means of nitric acid even as low in strength as sp. gr. 1.276 (13.6 per cent. HNO_3).

I have not been able to find any recorded experiments with sawdust, and the fact that it is largely employed for packing Winchesters of nitric acid in boxes, seems to show that it is regarded as a safe packing material. A few experiments which I have made may therefore be worth placing on record.

Of course, no one familiar with the properties of the strongest nitric acid would doubt that sawdust can be readily set on fire by it. The experiment is a favourite one for lecture demonstration, though, owing to the small quantities operated upon, certain precautions are necessary for success. Thus, the sawdust should have been previously thoroughly dried by heating it until it has begun to char, and to make success certain the sawdust should be warm. If a small paper tray, measuring about 3 inches square by

$1\frac{1}{2}$ inches deep, be filled with the dry and warm sawdust, and then about 20 c.c. of the nitric acid, prepared on the lecture table by distilling nitre with sulphuric acid, be poured upon it, first red fumes and dense white smoke appear, and in a few seconds the whole mass bursts into flame.

My experiments were made with weaker acid, chiefly of 1.40 sp. gr. (65.3 per cent. HNO_3) and 1.35 sp. gr. (55.8 per cent. HNO_3), and the sawdust was not dried in any way, but was used just as it came from the saw. A wooden box, measuring internally 6 ins. square by 12 ins. deep, placed within a larger box, 15 ins. square by 18 ins. deep, the space between them being packed with a non-conducting layer of sawdust, formed the apparatus. The sawdust experimented upon was placed in the inner box to a depth of about 4 ins. On this was placed a glass bottle about $2\frac{1}{2}$ ins. diameter and $6\frac{1}{2}$ ins. high, and the bottle was packed all round with the same sawdust and then withdrawn. Into the cavity thus formed the acid was poured, and then the hole was filled up with sawdust, and a loose lid was placed upon the top.

Expt. 1.—Pitch-pine sawdust used, and 1 quart of nitric acid of sp. gr. 1.43. This experiment was made in a large fume cupboard. At first red fumes and then dense white smoke appeared, soon followed by sparks projected from under the loose lid, as from a mild squib. Owing to the violent action, the fire was quenched at this stage, and the remaining experiments were made in the open air.

Expt. 2.—White deal sawdust, and 1 quart of nitric acid of sp. gr. 1.40. Red fumes; then dense white smoke. No flame; but on removing the lid the sawdust was found to be red hot, and the inside of the box was deeply charred.

Expt. 3.—Ordinary pine sawdust, and 1 pint of nitric acid of sp. gr. 1.40. Red fumes; smoke in 2 minutes; and on lifting the lid off the box at the end of 3 minutes the contents inflamed at once.

Expt. 4.—Oak sawdust, very fine and quite damp. 1 pint of nitric acid of sp. gr. 1.40. Red fumes in 1 minute; pale white smoke in 5 minutes; dense white smoke in 8 minutes. On lifting the lid the sawdust was seen to be red hot, and when stirred up it inflamed.

Expt. 5.—Elm sawdust, quite damp, from a freshly cut log. 1 pint of nitric acid of sp. gr. 1.40. Red fumes; much heat and steam, but no actual charring or smoke in half an hour. Then stopped the experiment.

Expt. 6.—Ordinary pine sawdust, and 1 pint of nitric acid of sp. gr. 1.352. Exactly the same result was obtained as in Expt. 3, but rather more time was required.

Expt. 7.—Oak sawdust, damp. 1 pint of nitric acid of sp. gr. 1.35. Red fumes. Pale smoke in 8 minutes, getting denser, but not very dense. Waited 15 minutes longer, and then removed the lid, and found the sawdust charred in places, but not red hot. Smoke and charring continued until the experiment was stopped.

Expt. 8.—Oak sawdust, dry, from a log two years old. 1 pint of acid of sp. gr. 1.35. Red fumes in 1 minute; smoke in $3\frac{1}{2}$ minutes, getting very dense. Contents of box did not appear to be red hot, and there was no flame on stirring, but plenty of charring and smoke occurred.

Expt. 9.—Elm sawdust, same as used for Expt. 5, but air-dried. 1 pint of acid of sp. gr. 1.40. Red fumes in 3 minutes; smoke in 6 minutes, getting very dense. Contents of box red hot, but no flame on stirring.

DISCUSSION.

In reply to a question by the Chairman, Mr. Archbutt said that he would recommend the use of kieselguhr or some similar absorbent material for the safe packing of bottles containing dangerous acids.

NOTE ON AN EXPERIMENT MADE TO DETERMINE THE PRESSURE OF ETHER AND SOME OTHER VOLATILE LIQUIDS IN CLOSED VESSELS.

BY L. ARCHBUTT, F.I.C.

I HAVE been induced to communicate this note by a question put to me by the President at our last meeting. About two years ago, my attention was directed to the iron drums used for the conveyance of large quantities of ether by railway, and it became necessary to ascertain the pressure to which such drums might become subjected in practice, owing to the expansion and increased vapour-tension of the contained ether caused by a rise of atmospheric temperature. The drums are not, of course, completely filled with ether, a space being left to allow for the expansion of the liquid; such expansion, however, would cause internal pressure by compressing the air in the space, and this must be added to the increased vapour-tension of the ether, due to the rise of temperature which caused the expansion. For several reasons, the combined effect could not be calculated, and it was necessary to make an experiment, for which purpose the following apparatus was devised:—

A glass bottle A (see figure) was fitted with a sound ordinary cork carrying the manometer M, and a short glass tube T, of about $\frac{1}{4}$ in. bore, not projecting beyond the cork inside the bottle. The cork was fixed firmly in the bottle, tied down with string, and well covered with sealing-wax. The bottle being empty and dry, mercury was first poured through the narrow tube T, into the short wide limb of the manometer, up to the mark M. The capacity of the bottle was then ascertained by pouring in methylated spirit from a measure until the liquid rose to a mark on the narrow tube T. The volume of spirit required was 550 c.c. The bottle and the manometer were then emptied, rinsed with ether, and dried by aspirating a current of air through.

In order to make an experiment with ether, mercury was poured, as before, into the manometer, and the bottle was

completely filled with ether up to the mark on the tube T, the mercury being adjusted to the mark M. The bottle was immersed up to the neck in running water at 50° F. and left there until the ether had acquired the temperature of the water, more ether being added to make up for the contraction due to cooling. In one experiment $\frac{1}{20}$ th and in another $\frac{1}{10}$ th of the total volume of the ether was then withdrawn by means of a pipette passed through the tube T, and a small cork was inserted in the tube as far as the 550-c.c. mark, and firmly fastened with string. The whole apparatus was now placed in a tall beaker containing sufficient water to completely cover the cork of the small tube T, and a thermometer was suspended in the water, which was heated up by a small flame and frequently stirred. When it was required to read off the pressure in the bottle, the mercury in the manometer was first adjusted to the mark M by pouring the necessary quantity down the long limb, and then the height of the column was marked in pencil on a narrow strip of paper gummed to the glass tube. The length of the mercury column between the two marks was afterwards measured.

In several experiments with ether, it was observed that the pressure slowly decreased on standing at a fixed temperature, owing to the air dissolving in the ether, and by raising the temperature rapidly a higher pressure could be obtained than by raising it slowly. By slow heating, the ether could be caused to expand until it almost completely filled the bottle, and as the slightest leakage of air would have been detected by the bubbles formed in the water, and none was seen to escape, there can be no doubt of the solution or occlusion of the air in the ether. In the following experiments, about half an hour was occupied in raising the temperature from 50° F. to 100° F., this range being regarded as sufficient. The liquids experimented with were commercial ether of, nominally, 0.725 sp. gr., the light petroleum naphtha known as gasolene, and the volatile liquid hydrocarbon condensed in the compression of oil-gas:—

Liquid.	Air-Space.	Pressure in Lbs. per Square Inch.	
		At 50° F.	At 100° F.
Ether.....	$\frac{1}{20}$ th	0	Lbs. 17.0
".....	$\frac{1}{10}$ th	0	14.1
Gasolene.....	$\frac{1}{10}$ th	0	13.0
Oil-gas hydrocarbon.	$\frac{1}{10}$ th	0	14.1

The liquids used gave the following results:—

Liquid.	Specific Gravity at 60° F.	Boiling Point.
Ether.....	0.7234	° F. 88 to 90
Gasolene.....	0.6596	82
Oil-gas hydrocarbon.	0.8084	66 rising very rapidly, First drop at 100° F.

DISCUSSION.

Dr. CLOWES mentioned some experiments which had been made to show the danger of sending cylinders of liquified ammonia from the Continent which were quite filled. Even mild steel cylinders had been burst by the expansion of the liquid caused by a comparatively slight rise of temperature under such circumstances.

The CHAIRMAN remarked that the application of safety-valves to the vessels or drums would appear to be necessary under such conditions. He asked if any of the members had experience of the ether light for lantern purposes, as an explosion had recently occurred when using this light, which he was disposed to attribute to the defective character of the safety-jet which had been used. It had been, however, considered that the high specific gravity of the ether was at the bottom of the mischief, which he was not disposed to agree with.

Dr. CLOWES said that he had met with cases in which an explosion had been caused by igniting air charged with vapour from a less volatile liquid, while air charged with vapour from a more volatile liquid of lower specific gravity did not produce an explosive mixture, owing to the larger amount of vapour present causing the explosive limit to be exceeded.

Mr. ARCHBUTT briefly replied, and then said that his note on "A Simple Device for checking the Loss of Iodine by Evaporation in Hübl's Test" had been anticipated in a paper by Dr. Schweitzer, of New York, in the last number of the Journal (Vol. 14, page 1934). He might say, however, that for several years he had used the simple device of sealing the stoppers of the bottles with a small quantity of a solution of potassium iodide, and, after they had stood the required time, simply rising this into the bottles before commencing titration. The solution on the stopper was invariably coloured yellow by iodine.

The CHAIRMAN asked what was the strength of the solution.

Mr. ARCHBUTT: A 10 per cent. solution.

Meeting held at the Yorkshire College, Leeds, on Monday,
January 27th, 1896.

MR. THOS. FAIRLEY IN THE CHAIR.

THE COMBUSTION OF COAL AND GAS IN HOUSE FIRES.

BY J. B. COHEN, PH.D., AND G. H. RUSSELL, A.I.C.

The object of the following experiments was in the first place to re-determine the extent of pollution of town air by smoke arising from house fires burning coal, and secondly to find if a more extensive use of gas fires might be recommended by way of mitigating or removing this evil.

Coal Fires.—A few determinations of the amount of soot given off from a good quality of Yorkshire house coal (Silkstone Haras) were made by Mr. G. Hefford, and appeared in a paper by Cohen and Hefford in the February number of this Journal, 1893. Cotton-wool plugs were employed for collecting the soot from the fire. Subsequently one of us found that the exceedingly hygroscopic character of cotton wool might, in view of the small quantity of soot in proportion to that of the wool, lead to appreciable errors unless dried and weighed with special precautions. Another source of error in the former determinations might have arisen from the fact that the carbon dioxide in the chimney gases was determined in samples drawn occasionally, and might therefore not accurately represent the average amount of carbon dioxide passing up the chimney during the whole period of combustion. It was consequently thought desirable to repeat the determinations so as to avoid these possible sources of error, and to extend them so as to include house coal from the Durham and Lancashire coalfields.

The results may be summarised briefly as follows:—

Using a similar kind of coal to that employed in the former determinations (there called A), the weight of soot per 100 litres of chimney gases and the per cent. of CO₂ were both found to be much lower than in the previous determinations. The net result has been to raise the per cent. of soot on the carbon burnt from 5 to an average of 7.7 per cent. on this particular quality of coal.

The average per cent. of soot in 12 analyses, including 8 of Yorkshire coals, 2 of Durham coals, and 2 of Wigan coals, amounted to $6\frac{1}{2}$ per cent. on the carbon burnt.

The quantity of soot obtained in different experiments with the same kind of coal varies, as will be seen from the table. It is no doubt influenced by the manner of firing and by the amount of draught. There was no slack in any of the samples.

The determinations were carried out as follows:—

The chimney gases were aspirated through a brass tube of about $\frac{1}{2}$ inch diameter. The end inserted into the chimney was closed and a narrow slit about 3 ins. long, was cut longitudinally at about 1 in. from the closed end, through which the chimney gases could be drawn. To the open end of the brass tube, a glass tube containing the weighed cotton-wool plug was inserted.

The cotton plug was dried in a weighing bottle in the steam oven, then kept overnight in a desiccator over sulphuric acid, and weighed against another cotton plug dried in the same manner along with the experimental one,

and the process repeated until consecutive weighings were constant.

The air was aspirated by means of two gas-holders, each holding about 15 litres, and the chimney gases were drawn off at the rate of about a litre a minute, which would approach the speed of the gases passing up the flue. The object of this was to prevent a greater deposition of soot in the brass tube than would occur in its progress up the chimney. Before reaching the aspirator a portion of the chimney gases was tapped by a smaller aspirator and made to pass through a drying tube and two weighed potash apparatuses. An average sample of chimney gases was thus obtained in which the CO_2 was determined.

In this way the operation was continued for about five to six hours, and during the time 200–300 litres of chimney gases were aspirated by the large aspirator, of which 5–20 litres were drawn through the small one. A good fire was maintained all the time, and the gases were aspirated from the first lighting of the fire.

The following is a tabulated statement of the results:—

No.	Carbon Dioxide.			Soot.		Per Cent. of Soot on C. burnt.	Name of Coal.
	Chimney Gases.	Weight of CO_2	Weight of C.	Chimney Gases.	Weight of Soot.

In column 4, the carbon in the carbon dioxide of the air calculated at 0.04 per cent. and measured at 20° , is deducted.

Gas Fires.—The use of gas in place of coal has often been suggested as a remedy for the smoke nuisance. Many people profess an objection to gas fires either from experiencing a real feeling of discomfort or from purely sentimental reasons. It has been alleged, moreover, that carbonic oxide is given off into the room from gas fires—a statement which, if true, would manifestly condemn their use. It is impossible to ascertain or explain the cause of, and therefore to controvert, sentimental objection; but the other points may be easily tested, *i.e.*, as to the evolution of carbonic oxide and as to the cause of physical discomfort.

Through the kindness of Messrs. Wilson and Sons, we have been able to test their gas stoves for carbonic oxide, and to make a rough comparison between three different species of gas stoves which they supply and coal fires as regards heating effect, from the point of view of economy and health.

We may say in parenthesis that we have no further object in naming Messrs. Wilson and Sons beyond acknowledging their readiness to supply us with all necessary apparatus and full permission at the outset to publish our results, whether prejudicial to their interests or not.

Carbonic Oxide.—We may state briefly that there is practically no carbonic oxide passing from a gas fire; *i.e.*, the volume does not amount to 0.01 per cent. of the flue gases with the full pressure of gas and burning 42–44 cb. ft. an hour.

When the gas is first lighted with slight explosion and the gases immediately aspirated for about two minutes from the front of the fire above the clay rings, an average of 0.9 per cent. of carbonic oxide was found.

Gases aspirated from within the clay rings contained on the average 10.5 per cent. of carbonic oxide.

We attach no importance to this, as, from experiments made at the College, samples of gases may be drawn from

the interior of a coal fire containing as much as 6 per cent. of carbonic oxide, none of which, with a reasonable chimney, ever finds its way into a room.

It will be readily understood that with a down draught unburnt hydrocarbons and carbonic oxide may be wafted into the room from a gas fire and probably also from a coal fire. The following tables contain the experimental results. A preliminary examination of the gases from the gas fires was made with Hempel's gas apparatus, by the palladious chloride and with hæmoglobin tests, with the following results:—

I.—Estimation of Carbonic Acid and Carbonic Oxide with Hempel's Gas Burette.

	Flue-Gases.		Gases from the centre of the Fire.
Carbonic acid.....	4.5 per cent.	4.7 per cent.	5.07 per cent.
Carbonic oxide.....	Trace	Trace	(not determined).

II.—"Palladious Chloride" Test for Carbonic Oxide.

Time of Absorption.	Flue-Gases.			Gases from top of Fire immediately after lighting.
	30 minutes.	45 minutes.	240 minutes.	74 minutes.
Indications of carbonic oxide due to blackening.	Very faint grey stain.	Faint grey stain.	Distinct grey stain.	Deep black stain.

III.—Hæmoglobin Test.

The flue-gases were aspirated through tubes containing calcium chloride, strong sulphuric acid, and soda lime, and finally through a flask containing a solution of blood.

Only the faintest indication of the presence of carbonic oxide was detected in *ten* litres of the flue-gases.

It was found possible, by this test, to detect with certainty less than 1 c.c. of carbonic oxide in *ten* litres, or 0.01 per cent.

We are indebted to Messrs. C. E. Brittain and H. de H. Boyd for carrying out the hæmoglobin tests.

IV.—Quantitative Determination of the Amount of Carbonic Acid and Carbonic Oxide in Flue-Gases.

In these experiments the flue-gases were aspirated through a brass tube of about $\frac{1}{2}$ in. diameter, inserted in the flue-pipe about 2 ft. above the aperture of the stove. The end

inserted in the flue-pipe was closed, and a narrow slit about 4 ins. long was cut longitudinally, through which the gases could be drawn off.

After passing the brass tube, the gases were aspirated successively through an empty vessel to condense moisture, drying-tubes, containing calcium chloride, and strong sulphuric acid, and eventually the carbonic acid present in the flue-gases was absorbed in the weighed potash-bulbs (A). After again drying, the residual gases were oxidised by passing over heated copper oxide in an ordinary combustion furnace, the water and carbonic acid thus formed being estimated by absorption in the calcium chloride tube (C) and the potash bulb (B) respectively.

The apparatus was finally connected up to an aspirator, and a gentle stream of gas maintained throughout each experiment, the total volume aspirated being measured in each case.

	I.	II.	III.	IV.	V.	VI.
Rate of consumption of gas, cu. ft. per hour	44.0	43.6	44.0	42.5	42.2	42.8
Volume of gases aspirated	6,000 c.c.	5,750 c.c.	1,750 c.c.	6,000 c.c.	5,100 c.c.	4,000 c.c.
Weight of carbonic acid (A)	Grms.	Grms.	Grms.	Grms.	Grms.	Grms.
Weight of carbonic acid (B) (oxidised carbonic oxide) ..	0.4235	0.4315	0.1125	0.473	0.4078	0.3172
Weight of water (C)	Nil.	0.001	0.0025	0.0067	0.0060	0.0048
Weight of water (C)	0.0105	0.0175	0.0125	0.0052	0.0058	0.0053

The percentage of carbonic acid is given from the weight of A. If the increase in weight of B is due to oxidised carbonic oxide, the percentages will stand as follows:—

Percentages.	I.	II.	III.	IV.	V.	VI.
Carbonic acid	3.58	3.83	3.26	3.91	4.05	4.02
Carbonic oxide	0.005	0.046	0.036	0.038	0.0385

Average per Cent.
Carbonic acid... 3.99
Carbonic oxide... 0.037

Owing to the large amount of water formed after passing the gases over the hot copper oxide, we concluded that either, (1) unburnt hydrogen, (2) saturated hydrocarbons, or (3) unsaturated hydrocarbons, were present in the flue-gases. We endeavoured to prove the presence of olefines in the gases by absorption with fuming sulphuric acid in a Hempel's gas-burette, with the following results:—

V.—Percentage of Olefines.

	I.	II.	III.	IV.	V.
Percentage	0.5	0.3	0.2	0.1	Trace.

It appears, therefore, that there is a small and variable volume of unburnt gas in the flue-gases, which will account for the formation of carbonic acid and water after contact with the copper oxide, and does not necessarily point to the presence of carbonic oxide.

VI.—Analysis of the Gases drawn from the Middle of the Fire.

	I.	II.	III.	IV.	V.	VI.
Weight of carbonic acid (A)	Grms.	Grms.	Grms.	Grms.	Grms.	Grms.
Weight of carbonic acid (B) (oxidised carbonic oxide) ..	0.009	0.0675	0.1455	0.340	0.067	0.213
Weight of water (C)	0.424	0.2035	0.5705	0.6985	0.327	0.3585
Weight of water (C)	0.0875	0.1595	0.2675	0.634	0.627	0.1025
Percentage of carbonic acid	Determined by Hempel's apparatus, 5.07 percent.					
Percentage of carbonic oxide	13.81	14.02	12.65	0.935	15.74	5.43

VII.—Analysis of the Gases from above the Clay-Rings immediately after lighting the Fire.

Carbonic acid	2.6	6.6	3.6	1.4
Olefines	Trace	Nil	Nil	Nil
Carbonic oxide	1.0	1.7	0.6	0.4

Comparison of the Heating Effect of Gas and Coal Fires.

Comparative determinations have been made with special reference to—

1. Rise of temperature of the air in different parts of the room.
2. Heating effect by radiation.
3. Dryness of the air.
4. Draught into the chimney.

The gas stoves tested were of the following kind:—

A. "Parisien" stove, the special feature of which is a perforated top, through the cylindrical apertures of which a constant circulation of air is effected, which then passes into and helps to warm the room.

B. "Comely" stove, similar to A, but without perforated top.

In both A and B the body of the stove is fixed in front of the old fire-grate, and the hot metal will assist more or less in warming the air.

C. "Canopy" stove. This is a new form of gas fire. It has eight instead of six atmospheric burners, as in A and B, but of rather smaller dimensions, and clay-rings; but it is fixed back in the old fire-place, and delivers not only its combustion products directly into the chimney, but the warm air from the hot metal also passes up the chimney. Further, it has a reflex and not a vertical fire-clay back, which is much longer than in A and B. In short, it is a shallow coal fire-grate burning gas and heating by radiation like a coal fire.

D. The ordinary old-fashioned coal fire-grate with vertical back, and both back and sides above the grate of cast iron. In moderately cold weather it consumes about 2 lb. of coal an hour; with hard firing that quantity would be doubled. Coal used was Haigh Moor best.

The gas-fires A, B, and the coal-fire, were tested on the same day and under approximately the same conditions.

Gas-fire C, which had not then been made, was tested on a later date along with B and the coal-fire.

The full details of the experiments will be found in the tables that follow.

The results may be briefly summarised as follows :—

Draught.—The chimney draught plays an important part in the heating of a room, and we will first refer to this :—

1. Although there is a rapid current of air, sufficient to extinguish a lighted taper, through the narrow exit into the flue of the gas-stoves A and B, which delivers the products of combustion to the chimney, the amount of air from the aperture only passes at the rate of about $3\frac{1}{2}$ cb. ft. per minute, measured by an anemometer.* The flow of air towards the front of a gas-stove was in these two cases so slow as to give no indication whatever with the anemometer.

Consequently, if the chimney space behind the gas-fire is blocked up, except for the flue-pipe, there is practically no ventilation of the room by way of the chimney.†

On the other hand, if the chimney is not blocked, the current of air is as follows :—

	Cb. Ft. per Minute.	
	Door of Room closed.	Door of Room open.
A burning 22—3 cb. ft. gas	105	123
B " " "	133	166
C " 20 " "	132	160
D " 2—3 lb. of coal { small fire. .	160	180
	200	235

Rise of Temperature of the Air.—The average rise of temperature indicated by thermometers (previously compared) and distributed through the room was as follows :—

	Mean Rise of Temperature in Degrees Centigrade.			Cb. Ft. of Gas burnt.
	1st Hour.	2nd Hour.	3rd Hour.	
A, January 3.	1'82	2'31	..	22½
B, " "	1'60	1'81	..	20
D, " "	1'00	1'37	1'4	..
				Moderately fired.
B, January 19	2'2	2'6	..	24
C, " "	1'4	1'6	..	19
D, " "	0'7	2'0
				Strongly fired.

The sets of experiments on the two days are not comparable, as the initial temperatures were very different, and the rise from the lower temperature in the second set was greater than in the first. As the room is over the kitchen, and gets a certain amount of heat from below, what was thought the least effective heating apparatus was tested last.

Dryness of the Air.—The first set of experiments were made when the outside air was nearly saturated with moisture (temp. 10·5; wet bulb 9·75). The difference between the wet- and dry-bulb thermometers in the middle of the room increased with rise of temperature of the air. The difference, as might have been anticipated, was greatest in the case of A and B in the first set and B and D in the second.

* The same anemometer was used throughout these experiments, and was roughly tested beforehand by fixing it on a long projecting plank in front of a railway carriage, driven forwards at a known speed, over an open track, on both up and down lines, for about five miles each way, so as to correct for the wind. The error of the anemometer for ten miles an hour was about 10 per cent. too low. We give the anemometer readings without corrections, as they are merely for comparison, and do not pretend to absolute accuracy. We have to thank the assistant engineer of the Lancashire and Yorkshire Railway, Mr. W. B. Worthington, for his assistance in making these tests.

† We have had no opportunity of testing the draught through gas-fire C, as it did not fit the fire-place, and air circulated around the sides and top and back. It would probably be much greater than in A and B, as it has a much wider aperture.

Difference between Wet and Dry Bulbs.

	Degrees.		Degrees.
A	5'0	B	5'3
B	5'0	C	4'2
D	4'5	D	5'2

Heating Effect by Radiation.—This was determined by suspending thermometers a yard from the fire at a height of 1 ft. and 3 ft. above the ground. There was little difference between the gas-fires and a bright coal-fire, except that the temperature was always rather higher near the floor than 3 ft. above in the case of the gas-fire, and often the reverse with the coal-fire. With an ordinary coal-fire a much lower temperature was obtained than with the gas-fire burning 20—23 cb. ft. an hour.

	1 Ft. above Ground.	3 Ft. above Ground.	
B	24'4	22'6	22—3 cb. ft. per hour.

D	24'5	24'5	Bright fire.
	19'5	20'2	Rather dull fire.

Gas-Fire Experiments.

The room measured 14 ft. × 14 ft. × 10 ft. high, and, in addition, a small bow window.

The thermometers were compared for correction and distributed as follows :—

- a. Middle of the room, 3 ft. from ceiling.
- b. Middle of the inside side wall, 4 ft. from floor.
- c. Middle of the room, 4 ft. from floor; wet and dry bulb.
- d. Middle of outside side wall, 4 ft. from floor.

January 3, 1896.—Wet and dry bulb outside indicated at midday: wet, 9·75°; dry, 10·5°.

Temperature outside varied during the day 10°—11°.

One person was in the room during all the experiments.

The temperatures given are in degrees centigrade.

"Comely" Stove.

The conclusions we arrive at from these experiments may be briefly stated as follows:—

1. The draught up the chimney plays an important part in the heating of a room.
2. If the fire-place behind the gas stove is closed, except for the flue-pipe, the greatest heating effect is produced; but there is then practically no ventilation by way of the chimney, unless by a special opening into it.
3. If the fire-place behind the gas stove is open, the draught up the chimney is considerable; but rather less than with a coal-fire.
4. In the last case the heating effect with gas stoves A and B is still greater than with the coal-fire, *i.e.*, the air of the room is warmed more quickly and to a higher temperature than with the coal-fire.
5. The heating effect of a gas-fire of type C is less than that of a coal-fire.
6. As regards relative cost in Leeds, roughly speaking, gas is three times as costly as coal comparing equal periods of heating; but, as regards heating effect, the cost of gas will be proportionately less. It is doubtful, even then, if gas is less than twice as expensive as coal.

There is no doubt that a higher heating effect with coal may be attained in modern modifications of the coal-fire on the "reflex" or "lean-to" back principle with small flue aperture, but we had no opportunity of testing this. In the case of a coal-fire the heating is mainly done by radiation and the air of the room is only slowly warmed by contact with walls, ceiling, &c., reaching, after a time, a maximum as is seen in the experiment on Jan. 3, when, during the third hour, no appreciable rise of temperature occurred. With gas stoves A and B, on the other hand, the air gets rapidly warmed and it is therefore necessary to guard against over heating of the air by ascertaining the temperature from time to time and adjusting the gas; for air warmed above a certain temperature is apt to cause a feeling of dryness and discomfort. If the fire-place behind the gas-fire is closed so as to get the maximum heating effect, some opening into the chimney should be contrived by making an aperture at the ceiling level. If the above conditions are observed, a gas-fire is a perfectly healthy heating appliance, more effective and more cleanly, although at the same time more costly than coal. It must be remembered that these experiments on the comparative heating effects of gas- and coal-fires, although carried out with as much care as the circumstances allowed, do not pretend to absolute accuracy. We believe that the general conclusions are correct.

DISCUSSION.

The CHAIRMAN said that it was difficult to make comparisons of the heating effects of the different fires on the same day, as the walls and other parts of the room accumulated heat slowly and only gave it out again slowly, thus tending to increase the effect in the later experiments. Much greater care was needed in the ventilation of a room heated by a gas-fire than when coal was used, owing to the smaller volume of air drawn through the room in the former case. He had found this volume about 10 times that of the gas burnt, while Dr. Cohen only found it about six times.

Prof. A. SMITHELLS said that the subject was one on which definite information was much needed. He had always been sceptical about the escape of carbonic oxide from gas-fires, but there was undoubtedly a difference in the hygienic effects of gas- and coal-fires. There was little doubt that where a flame burnt in contact with a cold surface, a certain amount of the gases escaped complete combustion, but in a gas-fire, where the combustion was in contact with a heated surface, this could hardly occur. It was true that Prof. V. Lewes had stated that unburnt gases (CO and C_2H_2) escape from a flame of coal-gas, burning freely in the air, but Mr. Lewis Wright and he himself had contested this statement, and Prof. Lewes had, in his last communication on the subject, admitted that the quantity was infinitesimally small, but still held that it might be sufficient to affect delicate constitutions. Dr. Cohen's experiments seemed, however, to show that the hygienic effects observed were rather due to the different ventilating effects.

Mr. W. McD. MACKEY thought that the main defect of gas-fires was that they did not secure efficient ventilation.

Mr. G. WARD thought that more satisfactory results would be attained if the experiments could be made with equal quantities of air passing up the flue.

Dr. J. B. COHEN, in reply to the Chairman, stated that he had purposely favoured the least efficient heating apparatus, viz., the coal-fire, by placing it last. Referring to Prof. SmitHELLS' remarks, he pointed out that the numbers which he had obtained showed that a gas-fire, when the fire-place behind it was not closed up, caused a flow of air through a room which was not very much smaller than that caused by a coal-fire. The difference in their hygienic effects was more probably due to the fact that the heating effect of a coal-fire reached a comparatively low maximum, while with a gas-fire the temperature might be raised much higher. If Mr. Ward's suggestion had been followed it would have defeated the object of the experiments, which was to find how the gas- and coal-fires as ordinarily used differed in their effects not only in heating but in ventilating a room. He also thought it was rather a grave error to regard a coal-fire as an efficient ventilating apparatus, for in the first place it produced a much more rapid exchange of the air in the room than is generally necessary, and secondly, this exchange is mainly near the ground, causing disagreeable draughts, instead of at the ceiling, where the ventilation is really needed.

APPARATUS FOR THE DETERMINATION OF THE RELATIVE LIABILITY TO SPONTANEOUS COMBUSTION OF OILS SPREAD ON COTTON WOOL.

BY WILLIAM McD. MACKEY.

In a paper read 30th Nov. last (Vol. XIV., 940) I described a method of examining cloth oils for their liability to spontaneous combustion when spread on cotton, but in the experiments then given I used an ordinary hot-water oven. Profiting by some of the suggestions made in the subsequent discussion, particularly one by Mr. F. W. Branson for an arrangement of tubes to induce a current of air, I have devised the apparatus now shown.

The apparatus consists of a cylindrical metal water-bath (this one is made of copper, tinned inside).

Section shown Fig. 1.

Dimensions:—Outside, 8 ins. high, 6 ins. diameter; inside, 7 ins. high, 4 ins. diameter. Pipes A and B, $\frac{1}{2}$ in. internal diameter and 6 ins. long, measured from the lid. The depth inside with the lid on is $6\frac{1}{2}$ ins. A lid (Fig. 2) packed with asbestos wool fits on the top, and the tubes A and B serve to ensure a current down B and up A. Care should be taken in using the apparatus that the steam from the water jacket is neither sucked down B nor warms A. C is a cylinder made of a piece of wire gauze (24 to the inch) 5×6 ins., forming a roll 6 ins. long and $1\frac{1}{2}$ ins. diameter. In the cylinder I place 7 grms. of cotton wool—ordinary

bleached cotton wadding—previously soaked with 14 grms. of the oil under examination, the wool occupying the upper $4\frac{1}{2}$ ins. of the cylinder.

Fig. 1.

Fig. 2.

The water being brought to the boiling point, a thermometer is inserted in the oily wool contained in the gauze cylinder, which is then placed in the bath, the thermometer being allowed to protrude through a cork in the opening shown in the lid. The bath is left boiling and temperature read after one hour.

In the following table I give the result of experiments on various oils:—

Oil used.	Temperature in 1 Hour.	Temperature in 1 Hour 15 Mins.	Temperature in 1 Hour 30 Mins.	Maximum.
				H. M.
1. Cotton-seed (12)	125	242	..	242 in 1 15
2. " "	121	242	282	284 in 1 35
3. " "	128	212	225	225 in 1 30

5. " "	116	192	200	200 in 1 30
6. " "	118	191	202	202 in 1 30
7. " "	117	190	194	194 in 1 30
8. " "	112	177	204	211 in 1 45
9. Olive fatty acids (3).	114	177	..	196 in 1 25
10. " "	105	165	..	203 in 1 55
11. " "	102	135	208	226 in 1 45
12. White Australian olein (13).	103	115	191	230 in 1 45
13. Olive (23)*	98	102	104	241 in 3 25
14. Olein (20)	98	101	102	110 in 2 8
15. 97 per cent. olein (17).	98	100	102	172 in 3 15
16. Belgian olein (19)	98	99	100	173 in 3 15
17. Olive (neutral) (21).	98	100	101	235 in 5 16
18. " "	97	100	101	228 in 4 30
19. " "	97	..	101	235 in 4 55

* Containing, roughly, 1 per cent. free fatty acids.

In my paper already referred to I pointed out that as a result of experiment with the apparatus I then used, any oil that either fired or attained a temperature of 200° C. in two hours might be regarded as dangerous.

In this table I give the result of experiments on some of the same oils (the numbers in brackets give the numbers for the same oils in table, Vol. XIV., 940). I should like to have included them all, but my stock of some of the trade oleins I had experimented on I found to be exhausted. I should state, however, that I give all the experiments made, so that 1 to 8, 9, 10, 11, and 17, 18, 19, form groups by which the reliability of the method may be judged.

From the results, then, of these experiments, I conclude that any oil tested in this apparatus, attaining a temperature of 100° C. before the expiry of one hour, may be regarded as dangerous. That would include 1 to 12.

These results tally with those given in my former paper, but the time for arriving at a conclusion has been considerably shortened.

I should state that I find the appliance very useful for testing various kinds of materials, such as oily waste, flocks, leather clippings, &c., suspected of being liable to spontaneous combustion.

DISCUSSION.

The CHAIRMAN said that the apparatus exhibited was very neat and compact, and the mode of experiment described was probably more trustworthy in its results than the actual firing of the oils, because if the heating were once checked it would not go on again. For experiments which were to be pushed to the point of actual firing, a larger apparatus would probably be more suitable.

OPIMUM ASSAY.

By D. B. DOTT, F.R.S.E., F.I.C.

OPIMUM being one of the most valuable of drugs, and the source of one of the most important of the alkaloids, its accurate valuation has attracted much attention, involving extensive experimental work. The alkaloids of opium vary in proportion, but the following percentages given by Pietet ("Alkaloides végétaux," p. 173) may be regarded as not far wide of the mark:—

Morphine	10
Narcotine	6
Papaverine	1
Codeine	0.5
Thebaine	0.3
Narceine	0.2

The morphine is usually in larger proportion. The alkaloids exist in combination with sulphuric and meconic acids. Although codeine is the only one of the minor alkaloids which is presently in constant demand, further uses may yet be found for some of the others or their derivatives. For instance, while narcotine is of feeble activity, hydrocotarnine, which can easily be prepared from it, has a decided physiological action. But whatever may be the case in the future, opium is at present invariably assayed by determining the amount of morphine which it contains. The processes employed for the purpose have undergone a gradual evolution, so that the methods now in vogue compare very favourably with those of the earlier years of the century. Some of these earlier determinations are quite misleading as the

crude precipitate weighed as morphine does not afford any accurate indication of the amount of that alkaloid actually present. Even now there is by no means unanimity of opinion or uniformity of practice in regard to this matter, although we are rapidly coming to a clear understanding of the subject. Generally speaking, the difficulty attending an accurate assay of opium may be stated: that on account of the chemical conditions in which the morphine exists in the drug it is impracticable to precipitate the morphine in the pure state without an undue and uncertain loss of alkaloid. Various plans have been proposed and tried to overcome this difficulty. Firstly and most obviously, the treating of the crude morphia precipitate with benzene and the like to remove impurities. By this means narcotine and its allies, codeine and resinoid are removed, but the residue is far from being pure morphine. Moreover, it is found that the precipitate obtained by rendering alkaline a mere aqueous extract of opium does not contain the whole of the morphine, or, otherwise, that the separation is so gradual and irregular as not to be complete in a reasonable length of time. Then came the device of adding a relatively large amount of alcohol, or mixture of alcohol and ether to the aqueous solution before precipitating with ammonia. By this means the morphine separates much more readily, in a more crystalline and purer form, than from the watery solution. Petit's process and Flückiger's earlier process partake of this nature. In practice, such methods are quite unsatisfactory. The loss of morphine is considerable, and varies so greatly with the quality of opium, temperature, and circumstances that a true correction for loss is impossible. The introduction of lime in assaying opium is generally attributed to Mohr, and appeared to be a decided improvement. A modification of this process was official in the 1867 British Pharmacopœia. The first improvement on the process was to abolish the boiling with the lime, which was an unwise and decomposing performance; and now, as improved by various chemists, it is a method widely used, and is official in the present British Pharmacopœia. Briefly stated, it consists in triturating a weighed portion of opium with excess of lime and water, filtering, taking what is supposed to represent half the opium, adding to it alcohol, ether, and excess of ammonium chloride, collecting the precipitated morphine, which is dried and weighed. The assay processes for opium being elaborate and troublesome it was very natural that attempts should be made to devise a volumetric method. Morphine is readily oxidised by iodic acid, ferrie salts, permanganate, and bichromate. Mylius suggested the use of iodic acid, relying on the amount of iodine liberated as equivalent to a fixed proportion of morphine. I have tried the addition of excess of bichromate of potash in acid solution and titration with standard ferrous sulphate. But there is uncertainty in all these methods. In the first place, we do not know how much of the oxidation may be due to impurities; and secondly, there is no evidence that a further or secondary oxidation does not occur. Iodine is so apt to react with alkaloids that its liberation from iodic acid by morphine does not appear as a promising plan for the estimation of opium. Even when working with pure morphine I have not obtained very constant or satisfactory results, but I have only tried a few experiments. The subject has not been by any means thoroughly worked up; it is sufficient to say that these indirect methods are not at present of any practical importance. What the analyst now wants, is to get hold of the actual morphine in as pure a state as practicable and weigh it. The method of Teschemacher and Smith ("Chem. News," lviii.) is one of the best for that purpose, and is much relied on. The official U.S. process is substantially the same, and in its present form is mainly due to Dr. Squibb. It consists in exhausting the opium with water, concentrating, adding alcohol, ether, and excess of ammonia; collecting the precipitated morphine, washing with alcohol and with water (both being saturated with morphine), drying, washing with benzene, drying, and weighing. A correction for impurities may be applied by treating with lime-water, which dissolves the morphine and leaves most of the impurities behind.

Considering the useful work that has been done in this subject by American chemists, it was very appropriate that among the first papers contributed to the New York

section of this Society were two able communications on the assay of opium. These were given by Dr. Wainwright (this Journal, 1895, 254), and Dr. Kebler, (this Journal, 1895, 464), and were followed by instructive discussion. I propose to offer a few further comments. In the first place, I would note that the morphinate of lime and ammonium chloride process, formerly official in the United States and now official in the British Pharmacopœia, was condemned by nearly all the speakers, mildly by Dr. Wainwright and emphatically by Dr. Coblenz. The latter stated that the students at college obtained such discordant results by the process that it had to be abandoned, while now by the Squibb method very satisfactory numbers are obtained. Speaking from a more limited experience, I entirely concur in the condemnation. In the first place, the idea of taking half the solution as containing half the morphine of the opium is a delusion and a snare. It is a striking example of the danger of going by theory instead of by experiment. If a given weight of water be added to the drug, the variable amount of soluble matters increasing the volume of the solution will cause appreciable error. Similarly, if the mixture be made up to a given volume, the varying bulk of the insoluble portion will cause some error. But there is some further source of error, and it seems to me to be this. It is well known that it is always difficult to extract the last portions of alkaloid from plant tissues. The process is very little analogous to the washing, say, of a sulphate of barium precipitate, where the chloride becomes quickly so attenuated as to give no perceptible reaction. A vegetable powder after long-continued percolation, still persistently gives up small portions of alkaloid, so that, as a rule, it is not practicable to completely exhaust. This reluctance to part with the latter portions of alkaloid may in some cases be partly chemical, from a small amount of the alkaloid existing as a nearly insoluble salt. It is probably, however, far more generally a physical question due to the manner in which the alkaloid or its salt is fixed in the plant cells, very much in the same way as it is difficult or impossible to thoroughly wash an alkaloidal salt out of animal charcoal. Seeing that the powdered drug does not readily yield its alkaloid even to repeated fresh portions of solvent, it will do so much less readily and very tardily when merely kept in contact with a comparatively strong solution of the alkaloid, so that in any practicable length of time, the drug will not have passed nearly all its alkaloid into solution. The next source of error is the large proportion of solution from which the morphine is precipitated. Morphinate of lime is readily soluble in water, but it is necessary to use a relatively large bulk of water, so that the errors from mass of material, as above referred to, may not be inordinately increased. Thence it results that slight differences in the solvent power of the liquid due to variations in temperature, manipulation, and other circumstances, must distinctly affect the yield of morphine, which is in small proportion to the mother-liquid. In the next place, the larger the amount of morphinate of lime, the greater will be the amount of ammonia liberated by the ammonium chloride, and thus the quantity of morphine held in solution will be increased. It is assumed that morphine is insoluble in ether, but I know that when freshly precipitated and presumably partly amorphous, the alkaloid is by no means insoluble in ether. This is just a possible source of error. Another point as to which there is some doubt, is the proper proportion of ammonium chloride. The amount always prescribed is much in excess of theory, and there is good reason to believe that this excess interferes with the precipitation of the morphine. After all, the morphine obtained in this process, though usually very pure, cannot always be assumed to be the pure alkaloid. Wherefore some process of purification or estimation must be applied, and that brings the method into the same category as others in which the precipitate is rather less pure, but can be readily estimated.

In comparing the related processes of Teschemacher and Smith, of Squibb, and of Flückiger, we have no hesitation in rejecting the last mentioned. Its weak points are the taking of an aliquot portion of the filtrate, too much dilution, and too much alcohol. Dr. Squibb's method has

the advantage over that of Teschemacher and Smith, that it prescribes more definite directions, which tend to constancy of results, and are to be commended in an official process. On the other hand, the Teschemacher and Smith's method has the advantage of greater concentration during the precipitation, which minimises the loss of alkaloid in that operation, and the decided merit of titration of the precipitate with standard acid. There has been some discussion in England as to the inception of the idea of estimating the alkaloid by standard acid, as if it were a recent invention. It was in constant use by the late D. R. Brown, of Edinburgh, 25 years ago, as I had frequent opportunity of observing. All the speakers at the American meetings referred in terms of commendation of the Squibb process, and deservedly so. Dr. Wainwright found the results by the 1890 U.S.P. process to be always higher and more constant than by the 1880 U.S.P. process; the greatest difference of percentage 9.2 : 7.3, and the least 9.4 : 9.0. Admirable as the method is, and altogether superior to that presently official in the British Pharmacopœia, it is still not above criticism. It is rather elaborate, requiring too great an expenditure of time for ordinary practical purposes. I think also it gives results rather under the truth, particularly if corrected by the lime-water treatment. To precipitate about 1 gm. of morphine from over 30 c.c. of solution, containing nearly one-third volume of alcohol and excess of ammonia, is not possible without appreciable loss. Of course there must always be some loss in precipitating an alkaloid like morphine, but the point is that the loss ought to be as small and as constant as possible. This is to be sought for in keeping the solution concentrated and avoiding a large proportion of spirit. The assumption that alcohol saturated with morphine cannot dissolve a further quantity of morphine is not to be implicitly trusted when the spirit has become charged with other matters, and the morphine precipitate may not be entirely in the crystalline state. There is a slight element of risk in this washing with morphiated spirit, more especially should the precipitate be exceptionally impure. Dr. Squibb found the impurity to vary considerably, as indicated by the lime-water test, and Dr. Wainwright found that in a sample of Persian opium the 16 per cent. of morphine indicated was reduced to 11 per cent. when corrected by treatment with lime-water, so that the precipitate which is being treated is not a constant factor. In the American discussion Dr. Squibb received general support in his contention that the morphine should be dried at 60° C., so as to avoid loss of water of hydration. The British Pharmacopœia is certainly wrong in its instruction to dry at 96°–100°, meaning obviously in a water-bath. It has never been the custom to reckon morphine in the anhydrous state. Moreover, morphine loses its water very slowly at the temperature of a water-bath. If anhydrous morphine is desired, then dry at 110° in an air-bath. Of course, if the morphine is to be titrated with standard acid, it does not matter whether it is over-dried or not.

Dr. Kebler's paper entered very fully into the amount and nature of the mineral matter found in the morphine precipitate, and on the determination of the ash as a means of correcting for impurities. Several years ago Dr. C. H. Warden analysed the ash of Indian opium, and found ("Chem. News," xxxviii., 146) the following percentages: — 1.98 Fe₂O₃, 7.13 CaO, 2.31 MgO, 37.24 K₂O, 1.76 Na₂O, 23.14 SO₃, 10.90 P₂O₅, 15.27 SiO₂. In 1881 I contributed a paper (Proc. R.S.E., Jan. 1881) on the salts of meconic acid, and showed how readily that acid forms a basic calcium salt. I have since proved that this basic salt neutralises acids, as one would expect, and that its formation should if possible be avoided, as leading to a slight error in titrating the precipitated morphine with acid. Dr. Kebler found in the morphine (U.S.P. 1890 process) 0.9 to 1.4 per cent. of ash; of the composition: —

Soluble in water (K ₂ CO ₃ , K ₂ SO ₄ , NaCl)	27.88
Silica	0.83
Aluminium phosphate	0.43
Magnesium phosphate	13.45
Calcium carbonate	56.17

It is evident, therefore, that even if the calcium existed wholly as basic meconate, the error in titrating would not

be very serious. But there is a more interesting fact brought out in Dr. Kebler's results, which might almost have been anticipated from Dr. Warden's analysis. I refer to the considerable amount of potassium salt found in the ash. Dr. Kebler does not indicate, but I think there can be little doubt that the potassium would exist in the precipitate as the sparingly soluble potassium-magnesium-phosphate, which would be decomposed when ignited with the organic salts. There would therefore be a small error due to neutral-phosphate in titrating with standard acid. It is difficult to suggest a means of getting rid of this trifling error, which is not open to objection. The slight error due to basic-calcium-meconate may be eliminated by adding a small quantity of ammonium oxalate before precipitating. By this means the calcium is thrown down as neutral-oxalate, which does not interfere with the titration. Dr. Kebler inclines to the belief that determination of the ash, after calculating the carbonate into meconate, is the best means of correcting for impurity in the morphine precipitate, but he admits that titration with acid is nearly as accurate, and much more expeditious. It is evident that in the case of a precipitate containing a good deal of organic impurity, estimation by standard acid would be the better way; while if the precipitate contained basic mineral matter it might be more accurate to correct by an ash determination. The idea of washing the precipitated morphine with lime-water is a good one, though somewhat tedious. By this means the alkaloid is entirely dissolved, and most impurities left behind. I have used baryta-water for the same purpose. Being stronger it has a more powerful solvent action on the morphine, but possibly it also dissolves more colouring matter. Treatment with lime-water or baryta-water may sometimes be useful as a check, but practically I think titration with decinormal acid is the best means for estimating the morphine precipitate.

In the "Pharmaceutical Journal" I have described two methods of opium assay, (XXII. 740 and XXIV. 847) which I have since slightly modified. As they appear to have some advantages, they may be here briefly described.

A. 10 grms. of opium are exhausted with spirit of "proof strength" (920 sp. g.). Evaporate to one-fourth volume. Dilute this with half its volume of water containing .05 gm. of ammonium oxalate, then cautiously neutralise with ammonia so as to leave just perceptibly acid. Allow to stand for an hour, filter, and concentrate to 8 c.c., then transfer to a flask or bottle holding 100 c.c. by means of 2 c.c. water and 3 c.c. alcohol, afterwards adding 2.5 c.c. solution of ammonia (960 sp. g.) and 25 c.c. ether. The flask is corked and shaken occasionally during the next hour. After 18 hours the ether is decanted as completely as possible, the precipitate collected on counterpoised filters, washed with morphiated water and dried. It is then washed with chloroform and dried about 60° C. Finally it may be titrated with standard acid. The success of this method depends chiefly on the careful neutralisation of the solution, avoiding any considerable amount of free acid on the one hand, and avoiding also, on the other, any precipitation of morphine. If these conditions are observed a very pure precipitate is obtained, the treatment with standard acid being almost superfluous. This method is very suitable for the estimation of tincture of opium. I have been accustomed to use neutral litmus paper as indicator in acidifying the morphine. Farr and Wright recommend to add excess of acid, and titrate back with $\frac{N}{10}$ soda, using methyl-orange as indicator.

B. 10 grms. of opium are digested with 30 c.c. water, until all soluble matter has apparently passed into solution. 1.8 gram barium chloride dissolved in 10 c.c. water is added, the mixture diluted and well stirred. It is then filtered, and washed till practically exhausted. The filtrate is warmed, dilute sulphuric acid added in quantity just sufficient to precipitate the barium, the solution filtered and set to evaporate, sufficient ammonia being added to nearly neutralise. When concentrated to 8 c.c. (.05 gm. ammonium oxalate added) it is allowed to cool, mixed with 1 c.c. alcohol and 1 c.c. ether, and then ammonia added till no further precipitate is produced, and a distinct odour of ammonia is present after stirring, and breaking down any lumps that

may have formed. After four or five hours the precipitate is collected on counterpoised filters, washed with morphiated water and dried. It is then powdered, washed with chloroform, dried and weighed. A weighed portion of the precipitate is neutralised with standard acid, and the percentage calculated. The former method gives a purer morphine precipitate which on that account is more easily accurately neutralised than that obtained in the latter method. On the other hand the neutralisation of the solution before concentrating, in order to precipitate resinoid, &c. must be carefully conducted. Should the addition of ammonia be carried rather far, acetic acid must be added to perceptibly acid reaction, so as to ensure that all the morphine is in solution.

The method (B.) has the advantage of being more expeditious, and requiring less work than probably any of the others. The precipitated morphine, however, contains much impurity, rendering the exact neutralisation with standard acid somewhat difficult. Yet it is a good practical process, and sufficiently accurate for most purposes. It may be modified so as to give a purer morphine by first exhausting the opium with water and then adding the barium chloride to the filtrate. This necessitates an additional filtration, but gives an ultimate precipitate containing less colour and impurity. In the case of a comparatively pure morphine, such as is usually obtained in the B.P. or U.S.P. processes, it may make little practical difference whether the correction is by treatment with lime-water or by acidifying with standard acid; but in the case of a less pure precipitate the difference is very marked, as the following figures show. The purified precipitate obtained in method (B.) above described, indicated by washing with baryta water 94 per cent. of morphine, while by titration with $\frac{n}{10}$ acid it indicated only 83 per cent. The same precipitate, after washing with morphiated spirit, indicated by titration 87.8 per cent. of morphine, showing that that method of purification is of very limited value in such a case. It is interesting to note that Dr. Squibb in his "Ephemelis" and Dr. Geisler at the New York meeting have both given numbers which confirm the truth of a note I published (*Pharm. Jour.*) some years ago, to the effect that the formula of hydrated morphine is $B_2(H_2O)_9$, and not BH_2O as generally stated. Dr. Geisler found 6.8 per cent. as the average loss on drying, $B_2(H_2O)_9$ requiring 7.1, and BH_2O requiring 5.9. This gives 305 as the equivalent instead of 303.

It was suggested by Rutherford Hill at one of the evening meetings of the Pharmaceutical Society, that amylie alcohol might afford a good means of separating the morphine in the assay of opium. That is a well-known method of separating small amounts of morphine and similar alkaloids in the analysis of medicines. I have tried it in several different ways, wet and dry, with quite unsuccessful results, largely due to the fact that morphine is very sparingly soluble in that menstruum. It seems scarcely possible to devise an amylie alcohol method which will offer any advantages either as to accuracy or expedition over the best of those presently in use. At least, that is the conclusion at which I arrived.

As regards the extraction of opium with water, my experience does not agree with that of Endemann. It must have been a very exceptional sample of opium which yielded a considerable amount of morphine to dilute sulphuric acid, after being practically exhausted with water. Excess of acid may facilitate the exhaustion, requiring less water for total extraction, but that is the most that can be said. At all events, I have never met with an opium which did not give an acid reaction, and it would be very strange if the morphine could not be extracted by water from such a drug. It is difficult to state exactly the amount of water required to exhaust a given weight of opium, as it depends on the manner in which the extraction is conducted, and on the degree of accuracy desired in the analysis. Less water is required if the opium is exhausted by the pharmaceutical method of percolation than if treated on an ordinary filter. As a rule I regard the 10 grms. of opium as exhausted when the filtrate or percolate amounts to 120 c.c., the opium having been digested with about 40 c.c. of water before percolating.

I append results of assay of a sample of Turkey opium by each of the methods referred to, the numbers representing percentage of morphine hydrate:

B.P.	U.S.P.	T. and S.	A.	B.
11.45	11.23	12.20	12.23	12.43

As regards the purity of the precipitate obtained in these processes, the first three were practically pure morphine, A. indicated 98 per cent. and B. 82 per cent. It is not to be inferred that the relative value of the methods is always exactly as indicated above. The B.P. process is specially liable to give varying results, and is generally relatively lower than above. A process which gives a different result, according as it has been conducted on a cold day or a warm day, or has been continued for 48 hours instead of 24, is of limited value. It is a great fallacy to attach value to a method because it gives concordant results in two experiments conducted under identical conditions. In practical working these conditions cannot be attained. This applies very truly to the morphinate of lime and ammonium chloride process presently official in the B.P. Quite recently several chemists working independently have obtained fairly concordant results with the methods A. and B., but considerable discrepancies with the method B.P. I agree with our American friends that it is not a trustworthy process, and that a process on the lines of the U.S.P. is to be preferred. At the same time I should prefer the method of Teschemacher and Smith, or that described as A., as representing more truly the full morphine-content of the opium, and giving nearly as pure a morphine precipitate. Indeed, if it is permissible to wash the variably impure morphine with morphiated spirit on the assumption that the precipitate loses no morphine or always a constant slight amount (a proposition which I doubt), then the T. and S. process is perhaps as good a one as we possess. I would only suggest the evaporation to a definite quantity, say, seven grams, instead of "a syrupy consistence," and the addition of .05 grm. ammonium oxalate before precipitating. The method A. has the advantage that the morphine is not exposed to the risk of washing with morphiated alcohol, most of the impurities being got rid of by having the morphine first in a spirituous and then in an aqueous solution, and particularly by neutralising the latter. The question naturally arises, may the results of these methods of assay not be vitiated by the presence of certain adulterants? It would be much more difficult to adulterate than at first sight appears. Any inorganic salt added with the intention of increasing the ammonia precipitate and neutralising the volumetric acid, would infallibly give a precipitate with the meconic acid and so draw attention to its presence by the unusual appearance. Probably all the cheaper alkaloids are soluble in chloroform, and would be removed on washing with that menstruum. I am not going to say what I think would be the most likely method of adulteration to escape detection. But in any case of doubt, it would be well to divide the morphine precipitate into three portions; one to be neutralised with standard acid, the second to be washed with baryta water, and the third to be incinerated and the ash weighed. By so proceeding it is scarcely possible that the result could be in error. In conclusion, I wish to express my indebtedness to the writers of the papers before referred to, and to those who took part in the discussions at the New York meetings.

MR. A. H. MASON IN THE CHAIR.

THE DETERMINATION OF CAFFEINE IN TEA.

BY E. H. GANE.

THE exact determination of caffeine in tea leaves is attended with great difficulty. Numerous processes have been devised, but as will be seen later, most of these have been based on inadequate information, and are valueless for the purposes intended. The process hitherto almost universally adopted is that devised by Paul and Cownley, which consists in treating the powdered leaves with MgO , and exhausting the dried mixture with alcohol. Two years ago, Allen in an exhaustive paper on caffeine (*Pharmaceutical Journal* LII., p. 213), hinted that this process was open to suspicion, the complete exhaustion with alcohol being in some cases impossible. Having occasion recently to determine the caffeine content of a large number of samples of tea, I have made a thorough study of the above and other processes, and the results are embodied in the present paper.

At the outset I would say that a large portion of my work has been merely confirmatory of the work published in Allen's paper, previously referred to, a paper which I venture to say has not in this connection received the attention it merited. This work may be briefly summarised as follows:—

1. Aqueous solutions of caffeine can be concentrated by boiling, and subsequently evaporated to dryness in a water oven without any loss of alkaloid.

2. Boiling caffeine with lime causes decomposition, the loss varying under different conditions from 20 to 50 per cent. Boiling with magnesia causes practically no change.

3. Admixtures of powdered tea leaves with lime or magnesia cannot be completely exhausted by percolating with solvent, such as chloroform, ether, &c. This fact was first pointed out by Paul.

4. Determinations of caffeine, based on treatment of the leaves with lime and subsequent boiling with water, are valueless owing to decomposition of the alkaloid.

As the above facts have been previously pointed out, a detailed account of confirmatory experiments is not necessary. Finally, as the result of my own observations, based on the examination of a very large number of samples of tea, I have come to the conclusion that the process of determining caffeine in tea by treating with magnesia and exhausting with alcohol, is open to considerable error and should be abandoned.

The difficulty met with in extracting caffeine from the leaves is probably due to its association in the leaf with other bodies, possibly, as suggested by Allen, in the form of a glucoside similar to that occurring in kola nuts; or possibly owing to combination with some tannoid body. Experiments with a view of elucidating this point have met hitherto with but little success.

Zoller (*Zeitschr. Anal. Chem.* XII., p. 106) supposes that the cellular structure of the tea leaf causes the obstinate retention of part of the caffeine, and has suggested a process based on the destruction of the cellulose with sulphuric acid and subsequent exhaustion with alcohol after neutralisation with lead oxide. This process gives accurate results, but owing to the retention of the caffeine by the charred tissue, prolonged treatment with large quantities of the solvent is necessary. This process is too tedious for every-day work.

Herlant's process, based on the solubility of caffeine in sodium benzoate is open to objection that complete extraction cannot be obtained under two weeks' time.

Squibb's process, consisting in boiling the tea leaves for a few minutes with magnesia, is one of the most satisfactory yet devised, the only objection being that the boiling is not continued long enough. Several hours' boiling is necessary to ensure complete extraction.

The method finally adopted as the most satisfactory, and as yielding the best and most concordant results, was that suggested by Allen. The process is as follows:—Six grms. of finely powdered tea are boiled with 500 c.c. of water, using a reflux condenser, for six hours. The decoction is filtered, and the filtrate made up to 600 c.c. Heat to boiling, and add 4 grms. of acetate of lead. Attach to a reflux condenser and boil for 10 minutes. Filter, take 500 c.c. and evaporate to about 50 c.c. Remove the excess of lead by means of sodium phosphate, and finally concentrate to about 40 c.c. The caffeine is then removed by shaking 4 or 5 times with chloroform. Four extractions are absolutely necessary to ensure complete extraction, and it is advisable to use a fifth.

This process I have found to give excellent results. Paul's objection to it that it does not extract all the caffeine seems to be unfounded, for after examination of over 50 samples of tea, I have not in any case found the process yield a less amount than the alcohol process, whilst in some cases it yielded considerably more. From the numerous determinations made, using both Paul's and Allen's methods, I have selected 12 samples as showing the variation in the two processes. The remaining samples yielded practically the same result by both methods. Appended the results are tabulated:—

Sample.	Yield of Caffeine.	
	Paul's Process.	Allen's Process.
	Per Cent.	Per Cent.
1. Black tea dust	2.51	2.55
2. Black whole tea, Japan	2.56	2.89
3. Black Anoy, whole leaf	3.06	3.14
4. Green dust	1.67	2.58
5. Black Congou, whole leaf	3.18	3.36
6. Green Hyson, whole leaf	1.11	2.10
7. Green sweepings	1.52	1.70
8. Black Assam	3.05	3.35
9. Green dust	1.24	2.22
10. Assam, whole leaf	3.93	4.01
11. Ceylon, whole leaf	3.98	4.12
12. Black dust, Japan	1.98	1.96

In the case of samples 4, 6, 9, it will be seen that the yield by Paul's process is very low, compared with that yielded by boiling with water. Complete extraction could not in these cases be obtained with alcohol, although 5 grms. of the tea and magnesia mixture were in these cases treated with 3,000 c.c. of alcohol. Even in ordinary cases, where complete extraction by this method is obtainable, from $\frac{1}{3}$ to 2 litres of alcohol has to be employed to secure extraction of 5 grms. of tea. This in itself makes the process objectionable from its expense. The residual caffeine could readily be extracted from the mixture by boiling with water.

The caffeine isolated by Allen's process can be obtained in a state of perfect purity very readily, but when using the alcohol process it is a matter of considerable difficulty to remove the whole of the green colouring matter. In all cases the residue obtained from the chloroformic solution was purified as carefully as possible. In the case of those obtained by Allen's process the residues were snow white and showed the melting point of caffeine. In carrying out this latter process I have found it advisable in some instances to continue boiling it with water for eight hours, though as a rule, six is amply sufficient. Owing to the slowness with which the decoction filters, I prefer to boil the tea with the whole of the 600 c.c. of water, and to add the acetate to the solution before filtration. This saves considerable time.

In conclusion I would say that the results above given show Paul's statement that water will not completely extract tea leaves to be erroneous. Allen's process is cheaper to work, less tedious, and gives more accurate results than Paul and Cownley's method.

DISCUSSION.

Mr. R. C. Woodcock said that some years ago he had a number of estimations of caffeine to make, and that he

boiled the tea with dilute acid and treated it with magnesia and made the extraction afterwards with alcohol, a most troublesome process. It occurred to him that perhaps the Prolius method might be applied for this purpose; but the difficulty was to break up the combination with the tannin.

Dr. H. SCHWILTZER asked Mr. Gane whether he had tried any other solvents than ether, chloroform, and alcohol for the extraction of caffeine, and whether it was not possible to extract those 5 grms. of tea in the Soxhlet apparatus instead of using 4 or 5 litres of alcohol?

The CHAIRMAN said that Mr. Gane evidently very closely agreed with Mr. A. H. Allen in the whole of his investigations. In some of his statements he thought Dr. Paul agreed with Mr. Allen. The results which Mr. Gane obtained from his samples of tea were very low in comparison with what he had seen reported elsewhere, for whereas by the water process Mr. Gane only spoke of 1.41 as the yield, it had been found as high as 4.30. The only alteration Mr. Gane would recommend to Mr. Allen's process was that the extraction be continued for eight hours instead of six. He considered this subject of great importance to those interested in chemical industries in America. Caffeine was imported to an enormous extent, and if it could be made by such a simple process without the use of alcohol, and enough of it obtained from the sweepings of the tea warehouses, he saw no reason why it should not be manufactured in the United States. He would also like to ask whether acetone had been tried.

Mr. Jas. HARTFORD agreed with the Chairman as to the increase in the consumption of caffeine. Within the last four years it had grown enormously, and it was a matter of surprise that it had not yet been manufactured in America. Two firms had undoubtedly started its manufacture, but gave it up, for what reason he did not know. At that time caffeine was just as dear as it is now. With regard to the sweepings of tea warehouses they did not now play such an important part as formerly, for the demand for caffeine had gone beyond the supply from this source, and the manufacturers now used damaged tea as their raw material.

Dr. G. M. STILLWELL said that his experience was that the extraction of these soluble compounds was facilitated, not by contact with the solvent itself, but with its heated vapour. The solvent did not remain continuously in contact with the material, but was boiled, and the hot vapour passed up through the material and was then condensed again.

Mr. GANE said in reply, that he had tried extracting the tea by boiling with dilute acid, but with no better result than by simply boiling with water. By using alcohol for extracting according to Paul's method it was extremely difficult to get rid of the green colouring matter, as it required several solutions and precipitations to remove it. In reference to the yield, the illustrations he gave were samples of tea dust and could not yield more than 2 or 3 per cent. In some cases the yield from tea had run up to 4 and even 4½ per cent. The tea which was imported into America (mostly Chinese) yielded less than the Ceylon teas reported upon in England. In reference to the manufacture of caffeine in America, he doubted if it were possible, on account of the low yield of caffeine for one reason, and also on account of the small amount of refuse tea obtainable. Very little damaged tea arrived; the bulk being of high price, and of a quality which it did not pay to use for extracting caffeine. The Prolius method he had not tried. He had tried the Soxhlet process, but when mixing the tea with an alkali it was advisable not to apply heat. A better extraction was obtained by using a cold solvent.

Mr. A. H. ALLEN writes that Paul and Cowley's process was the only one previously published by which fairly reliable determinations of caffeine in tea could be made; and he confirms the observation that when tea is made into a paste with lime or magnesia and water, and dried at 100°, chloroform fails to extract the whole of the caffeine, however continued the treatment. Paul and Cowley stated that when magnesia was used alcohol effected complete extraction, their proof of this being that subsequent treatments with alcohol failed to extract more alkaloid. Allen finds that on then treating the mixture with water more caffeine is dissolved out, sometimes in small quantity, but in

other cases as much as 10 per cent. of the whole. Continental chemists still profess to give the total caffeine in tea, though their methods are now proved to yield only from one-third to two-thirds of it.

BESSEMERIZING NICKEL MATTE.

BY H. W. EDWARDS.

From 1891 to 1894 the writer was in charge of a nickel smelting plant, situated near Sudbury, Ontario. The plant consisted of two blast furnaces and a set of Bessemer converters (Manhes' modification) with all the usual equipment.

The ore to be treated for the extraction of the nickel was very typical of the district, a massive pyrrhotite, magnetic iron pyrites, containing in its pure state about 1 per cent. nickel, which occurred as a replacement of an equivalent quantity of iron; copper also occurred to the amount of 2 per cent., in the form of chalcopyrite. As delivered to the furnaces the ore contained about 60 per cent. pyrrhotite and about 40 per cent. gangue, an easily fusible diorite, the assay of the stock thus standing at about 2.4 per cent. nickel and 1.2 per cent. copper. The greater part of the iron in the ore was oxidized by burning in heaps, in the usual way, there being nothing remarkable about this part of the operations except the great size of them. Heaps of 2,000 tons were common and 1 once built one containing upwards of 4,000 tons of ore. Such a heap would burn four to six months and smaller ones eight to 14 weeks. The sulphur contents would be reduced from 22 or 23 per cent. down to 5 or 6 per cent. This burnt ore was fused in the blast furnace in the usual manner at the rate of 90 to 100 tons daily. The products of the blast furnace operation were a slag consisting of a mono-silicate of iron containing from 0.1 to 0.2 per cent. nickel, and a matte containing from 10 to 15 per cent. nickel, 5 to 7½ per cent. copper, both present as sulphides and 65 to 75 per cent. sulphide of iron. It was required to oxidize in the converter the whole of this latter component, or as much of it as could be accomplished in one operation. The blast furnaces were elevated some 6 feet above the general floor level of the smelting shed, each upon a terrace secured by stone retaining walls. We were thus enabled to arrange for the molten matte to run direct from the blast furnaces to the converter.

The converters were of the ordinary Manhes' type mounted upon a travelling carriage. This type has been several times figured in technical publications (for example "Engineering and Mining Journal," New York, Volume 52, page 307) so that it is not necessary to illustrate it again in connection with this paper. Its leading dimensions were—length 7 ft. 3 in.; diameter 5 ft. 8 in.; number of twyers 12; diameter of twyers ¾ in.; capacity, newly lined, 1½ ton, with an old lining three tons. The blowing engine was a double cylinder, simple slide-valve, length of stroke 30 in.; diameter of air cylinders 28 in.; diameter of steam cylinders 16 in.; 25 revolutions per minute would maintain a pressure of six pounds of air per square inch when blowing one converter.

The lining of the converters is the principal point upon which the economical success of the process depends. Its function is not only to protect the body of the converter from fusion, but to supply silica for the formation of a silicate of iron slag. All attempts hitherto (and my experience agrees with that of others), to supply silica in other ways have proved fruitless. If thrown in loose during the progress of the operation the silicious flux merely floats upon the surface of whatever slag is present and has little or no chance to come into contact with the ferrous oxide being formed at the lower portion of the charge. If supplied below the surface, through one or more twyers along with the blast for example, it immediately floats up to the surface of the slag, a small pro-

portion only being able to combine with ferrous oxide during its momentary passage upward. There are also mechanical difficulties in the way of this latter course. Meanwhile, until persistent effort shall result in a better system, it is important to have a cheap supply of satisfactory silicious material. Quartz, sandstone (if sufficiently infusible), or quartzite give excellent results crushed to pass through a sieve having openings of $\frac{1}{4}$ in. or $\frac{1}{2}$ in. in diameter. At Sudbury I used tailings from an abandoned copper mine some 75 miles distant along the railway. These tailings consisted almost entirely of white quartz containing occasional particles of chalcopryite. The material had been pulverised to pass through a sieve of four holes per linear inch.

Analysis of a typical sample—

	Per Cent.
Magnesia.....	1.2
Alumina.....	1.7
Copper.....	0.6
Iron.....	1.7
Sulphur.....	0.35
Moisture.....	4.75
Silica, by difference.....	89.6

Another sample showed 1.2 per cent. copper.

The other ingredient of the lining is clay. Its office is merely to supply the plasticity permitting the mixture to be moulded to the correct shape for forming the lining and holding it in place; of course it has to be an infusible variety. Plasticity is as important as infusibility since, everything

else equal, the more plastic the clay the more quartz can be incorporated into the mixture. Both qualities, plasticity and infusibility, should be of a high order as they have a surprising effect on the life of a lining, the most expensive clays not infrequently giving the cheapest results. Below I give a table showing the costs of 130 linings made of 13 different mixtures with various kinds of clay and quartz.

Description of clays:—

No. 1. White sandy clay containing some undecomposed felspar (albite), slightly fusible at incipient white heat; plasticity moderate: cost per ton delivered at the works, 3 dols. 75 cents.

No. 2. A red clay containing much oxide of iron: very plastic: softens at a full red heat: cost per ton delivered at the works, 4 dols.

No. 3. A grey coloured clay from Silver Creek, Ohio: very infusible: more plastic than No. 1, but not so plastic as No. 2. Cost per ton delivered, 5 dols.

No. 4. From Stourbridge, England: very plastic and very infusible: cost per ton at works, 10 dols.

Description of Quartz:—

A. Massive milky white with much (about 20 per cent.) albite. Cost per ton at works, crushed, $3\frac{1}{2}$ dols.

B. Tailings from the Bruce Copper Mine. Cost per ton delivered, $2\frac{1}{2}$ dols.

C. River sand, very fine, silica 97 to 98 per cent. Cost per ton delivered, 2 dols.

D. Glassy quartz, very pure. Cost per ton delivered at works, crushed, 4 dols.

Mixture.	Clay used for 10 Linings.	Quartz used for 10 Linings.	Cost of the Clay for 10 Linings.	Cost of the Quartz for 10 Linings.	Number of Charges blown on the 10 Linings.	Cost per Charge blown.		
						For Clay.	For Quartz.	Total.
						Dol. Cents.	Dol. Cents.	Dol. Cents.
Clay No. 1 with Quartz A.....	Lbs. 13,500	Lbs. 37,000	Dol. Cents. 25 31	Dol. Cents. 64 75	53	. 48	1 22	1 70

* Three linings failed altogether on blowing their first charge—want of adhesion.

† In these two cases the clay was mixed to a slurry, and then crushed quartz added. All other mixtures made by mixing dry pulverized clay with crushed quartz.

‡ Estimated weight.

§ Four linings had to be rebuilt before converters left re-lining shop, the overhanging parts falling away while drying.

The quartz and clay, together with sufficient water, are thoroughly mixed in a mortar-mill, or in an ordinary brick-pug-mill. The wet and plastic mixture is rammed into the converter to the proper thickness, and dried in the usual manner.

All the foregoing remarks apply equally to lining converters for Bessemerizing copper matte. Owing to the high percentage of sulphide of iron in low-grade nickel matte the question of linings is much more important than with copper matte where they often have no more than 20 per cent. of sulphide of iron present.

The molten matte is accumulated in the blast furnace in a suitable reservoir, and the converter is placed in position. On tapping the furnace the matte runs into the converter by an iron trough coated with clay. The only objection to this direct method as opposed to its alternative, casting the matte into pigs and remelting it specially for the converters, arises from the inconvenience of not knowing the relative quantities of nickel, copper, and iron sulphides present in the charge. The blowing would be over before one could make any satisfactory assay. Nevertheless, with practice, a fairly regular product was turned out.

The converter, now charged, is wheeled to a bell-mouthed iron chimney, supported on four pillars, where the blowing operation is conducted. Air connection between converter and engine is made by a pair of well-finished flanges fitted

with three bolts and thumb-screws, one flange fixed upon the twyer-box of the converter, and the other to 3 or 4 feet of leather hose leading from the air-receiver. The engine is now started and the twyers immersed beneath the surface of the charge by partial rotation of the converter. The process proper now commences.

Starting with a pressure of air 5 lb. per sq. in., the first stage is marked by brilliant scintillations from the mouth of the converter accompanied by little or no flame or fumes, the agitation being at first very violent, in fact more violent than later on at 7 lb. The brilliant display usually lasts five to ten minutes, but is occasionally much prolonged if the amount of sulphide of iron exceeds 70 per cent. of the charge, and the action would be more violent in proportion as the initial temperature of the charge is higher, and also to the size of the charge. In such circumstances the blast pressure is reduced, sometimes as low as $3\frac{1}{2}$ lb. per sq. in., and the twyers raised so as to present less resistance. I usually found a height of 30 in. of matte above the twyers gave the best results, but in the case of such violent action as I have just mentioned we sometimes had to work for a while with only 10 in. The quieting down was aided by the addition of cold matte to the charge, sometimes in surprising quantities, 30 per cent. of the weight of the charge in more than one instance, all of which would be fused by the heat developed.

The first stage of the operation being over, white fumes and flame begin to appear. The air pressure is then raised to 7 lb. per sq. in., and the twyers immersed to their deepest below the surface of the charge. Now the temperature of the charge begins to rise rapidly, and at this period part of the sulphur seems to be given off as SO_3 , while when the temperature has reached its maximum, or increases but slowly, the proportion of SO_2 appears to diminish or cease. SO_2 is, of course, given off copiously all the time. The flame at first is red; but as the temperature increases it becomes blue or green according to the size and temperature of the charge. The appearance and colour of the flame is no indication of what is going on inside the converter; it can be relied upon only for negative indications. So long as the flame is red, or has any red or pink border, and so long as white fumes are mingled with the flame, there is still a considerable amount of iron in the converter as yet unoxidized; but as both of these appearances cease when the operation is but little more than half accomplished, they are not much practical guide. As the operations progress the fumes decrease and finally cease, leaving the flame of a transparent blue or green colour which is maintained to the end. The end of the operation is judged rather by a perceptible diminution of temperature, not only of the flame, but also of the particles splashed or blown out of the converter, and by the appearance of these particles, which gradually become more frothy, and at last issue in flakes about the size of the open hand. The twyers are then raised above the level of the charge and the blast stopped. After a few moments' rest, to permit the slag and enriched matte to separate, the slag is emptied off, by rotation of the converter, into cast-iron pots, and the rich matte, so far as possible free from slag, into separate pots. The resulting rich matte usually contains but little sulphide of iron, sometimes less than 2 per cent. The slag consists of silicate of iron, the silica being derived from the quartz of the lining, as before explained. The lining lasts from five to seven charges, when it has to be renewed, that is to say, sufficient quartz and clay rammed in to bring the interior cavity of the converter to its original size. For this it is not necessary to remove any more of the old lining than will give a solid bearing for the new material.

The amount of nickel oxidized is trifling, the copper and nickel in the slag being invariably present in the same proportions as in the original and final matte, showing it to be due merely to grains of matte entangled in the slag.

ANALYSIS OF THE RESULTING PRODUCTS.

Final Matte.

	Per Cent.	Per Cent.	Per Cent.
Nickel sulphide	63.8	64.7	64.9
Copper sulphide	32.4	32.1	33.8
Iron sulphide	3.8	3.2	1.3

Slag.

	Per Cent.	Per Cent.
FeO	66.6	67.1
SiO_2	28.5	27.9
Cu	1.1	0.8
Ni	1.9	1.6
S5	.4

Cobalt when present is perfectly scorified with but little oxidation of nickel, forming a very ready means of commercially separating these two metals. Zinc, antimony, and arsenic in particular are completely volatilized. Bismuth, silver, and gold are completely concentrated along with the copper and nickel.

In treating a lot of very cupreous ore containing copper about 8 per cent., and nickel about $1\frac{1}{2}$ per cent., I succeeded in producing in the converter a crude metallic alloy containing copper 76 and nickel 15 per cent. Another lot from ore slightly different, gave an alloy of 68 per cent. copper and 28 per cent. nickel. Several carefully arranged experiments with ore of similar tenour indicated that with proper modifications, there would be no difficulty in regularly producing a crude metallic alloy of half nickel and half

copper, or two-thirds nickel and one-third copper. The principal modification I would recommend would be the considerable increase in the size of the converters, say, to 5 tons per charge, in order that there might be a greater quantity of heat developed, so that the increased temperature required by the nickel alloy may be attained. It is in some such manner as this that we may hope for cheaper supplies of nickel from the Sudbury district, where immense water power is available for the electrolysis of a crude alloy so obtained. I see no reason why nickel could not be put on the market in some such way as this for about the same price as copper, supposing that the latter were being produced from an ore of similar richness.

The slag from the converters is in every instance returned to the blast furnace along with succeeding quantities of burnt ore. 1,264 tons of coarse matte, containing an average of 70 per cent. sulphide of iron, yielded 300 tons of bessemerized matte, and 1,356 tons of slag. As all the latter product has to be remelted, it will be evident that any efforts to diminish the proportion of slag produced by the converters, will, if successful, have a very important bearing upon the industrial aspect of the process. It naturally occurs to the mind that a basic, or at least neutral, lining in the converter would be beneficial. Unfortunately my experiences with basic linings were not very successful; and I believe repeated experiments by others, treating copper mattes by this process (some of whom had much more favourable conditions than I could command at Sudbury), have been failures. According to my own experiences one great obstacle would seem to be the retarding of the process itself. For example, a normal charge, estimated to require 50 minutes blowing on the ordinary siliceous lining, required $1\frac{1}{2}$ hours on a lining of lime. Such a retardation of the process it will readily be perceived almost halves the capacity of the converter plant while the running expenses for labour and steam power are unaffected. It is rather an interesting feature, and one worthy of a critical examination, this delay in the oxidation of the sulphide of iron in a case where there is no substance at hand to combine with the ferrous oxide as soon as formed. I attribute it to the reduction of the ferrous oxide to the metallic state by the undecomposed ferrous sulphide, a portion of the iron thus having to be oxidized twice over; the reduction, of course, absorbing heat, which still further delays matters, a hot charge being essential for rapid work. A few linings of crushed coke and clay gave, as would be expected, even poorer results, reduction of iron again no doubt. As before explained, efforts to add siliceous flux through the mouth or twyers were not encouraging.

Several years ago details of experiments in this process were published, see "Engineering and Mining Journal" New York, December 29th, 1883 (which quotes from "Le Genie Civil"). I am not able to follow the figures quoted as the results of M. Jules Garnier's experiments. This gentleman appears to have lost half of his copper while obtaining a very satisfactory enrichment of nickel. This is quite contrary to my own experience. Here are his figures. Starting with 50 lb. charges of nickel matte from Sejeu, Norway, containing nickel 16.3 per cent., and copper 5.86 per cent., he gets—

	Per Cent.	Per Cent.
After blowing 5 minutes	Cu 11.00	Ni 30.73
" 10 "	Cu 14.13	Ni 50.80
" 15 "	Cu 11.3	Ni 70.06

the iron being reduced from 22.4 per cent. in the original material down to 1.2 per cent. after blowing for 15 minutes. In the slags he gets:—

	Per Cent.	Per Cent.
After blowing 5 minutes	Cu 0.05	Ni 1.51
" 10 "	Cu 0.50	Ni 3.0
" 15 "	Cu 0.3	Ni 4.0

Now to preserve the same ratio of copper to nickel that he had in his initial charge, he should have finished with a matte of 19.48 per cent. Cu after 15 minutes' blowing, and

not 11.3 per cent. The fact that M. Garnier reports 0.3 per cent. copper in his slag at the end of the operation does not account for it unless his 50 lb. initial charge yielded something like 9 cwt. of slag. Experiments of this kind are not very useful to the general public unless the experimenter publish not only the analysis of his various products, but the weight of each product also.

Another notice in the "Annales Industrielles," 1885, page 290, is about a dozen lines in length announcing that M. Pierre Manhes proposes to treat nickel and cobalt mattes in his recently patented converter for the production of a rich matte free from iron.

These two notices are the only references I can find, and, I think, constitute the literature of the subject up to date.

DISCUSSION.

In reply to a question from the Chairman,

Mr. EDWARDS stated that they had no rapid method for detecting nickel, especially in the presence of a large amount of iron.

AMERICAN PHOSPHATES IN 1895.

BY SAMUEL PEACOCK.

THE annual consumption of commercial fertilisers in the United States is something above two million tons, making use in its manufacture of about 600,000 tons of crude phosphates. Of this quantity about 60,000 tons are imported in the form of phosphatic guanos and the phosphates of Curaçao, Grand Comnetable, &c. The deposits of North Carolina supply about 9,000 tons, and Canada still sends a few thousand tons of apatite over the border. The greater part of the 600,000 tons of phosphates comes from the deposits in Florida, Tennessee, and South Carolina in the following proportion:—

Florida	15
Tennessee	10
South Carolina	75

The quantity mined in 1895 was much below that of 1894, Tennessee alone showing an increased production. On January 1st, 1895, the total Tennessee production had not greatly exceeded 15,000 tons; the production of 1895 was very nearly 50,000 tons.

Though there are many deposits of phosphates in the Western hemisphere, only those in the United States are of considerable importance, so far as is yet known, of which Florida, Tennessee, and South Carolina are the chief. These three deposits have special characteristics, which will serve to keep them all in operation, though any one of the three could perhaps easily supply the whole demand. South Carolina produces a relatively low-grade phosphate, which by ordinary acidulation processes makes an acid phosphate containing from 12 to 14 per cent. soluble phosphoric acid. The situation of the deposit is very favourable for water transportation to all the large cities on the Atlantic coast line, and it is at these cities that the great bulk of the commercial fertilisers are manufactured. Thus, South Carolina must always hold a fair share of the coast-line trade, but it can hope for but little of the consumption of the interior or the foreign demand.

Florida produces a higher-grade phosphate, well adapted for the requirements of the foreign markets, as it is suitable for the manufacture of concentrated superphosphates. Through the five shipping ports, Tampa, Brunswick, Savannah, Fernandina, and Punta Gorda, the foreign market is easily reached, but the local transportation from the mines to the ports is limited by traffic charges.

Tennessee supplies the best crude phosphates of the three fields. It is not only high grade and works up well under the crude manufacturing methods in this country, but it is very cheaply mined and occupies an excellent position for distribution. The fertiliser consumption in the States west of the eastern coast range is rapidly increasing, and the Tennessee phosphates will supply almost the total demand. Of all the three fields, Tennessee alone was practically sold up on the 1st of January; in fact, the

output of 1895 would have been much larger but for a lack of freight cars for shipment. The stocks on January 1st were less than 4,000 tons.

Whatever may have been the cause, and there are many reasons assigned, the American phosphate trade of 1895 was very unsatisfactory. Twelve months ago the (Charleston, S.C.), prices were approximately 3.75 dols. to 4 dols. for crude rock, 4.25 dols. to 4.50 dols. for hot-air dried rock, and 6.50 dols. for ground rock. At present the prices quoted are 2.75 dols. for crude, 3.10 dols. for hot air dried, and 5 dols. for ground, and extensive sales have been made below these figures. The trade conditions at present are such that in South Carolina many of the mining companies have closed their works indefinitely, and the State phosphate inspector recommends a reduction in the royalty of one-half.

In Florida the conditions are scarcely better. Since January 1895 the ruling prices have dropped from 1d. to 1½d. per unit—1.50 dols. to 2 dols. less per ton. Within this month sales are reported as low as 1.90 dols. per ton, which is very probably below *f.o.b.* cost to most of the mines of the State. While the Florida shipments have about equalled those of 1894, the stocks are reliably reported as still very high. At present many of the mines are closed pending some systematic arrangement of the business. Several attempts have been made towards an organisation of the various mining interests, but the condition of the industry at present is such as to practically defeat the best intentioned efforts. There are many small operators who merely surface mine on a royalty, and who abandon the work when the cost of extraction begins to increase. While the individual output may be small, the aggregate counts heavily in the trade, and is used by the manipulators to bear prices.

In Tennessee the producers are hampered somewhat by a lack of capital; a condition likely to be short lived. Production is under the orders, and the immediate business prospects are good. This field is destined to play a very important rôle in the domestic consumption. The annual supply of bone and packing-house phosphates is even now inadequate to supply the fertiliser demand of the West, though this production amounts to above 150,000 tons per year. The fertiliser manufacturers of this section are compelled to use mineral phosphates, and the Tennessee deposit will obviously supply the demand.

DISCUSSION.

Mr. H. W. EDWARDS said that he thought the exports of phosphate to Europe would be largely affected by the increased use of basic slag. Since the introduction of the Thomas-Gilchrist process there had been many thousand tons of this slag produced, the bulk of which was available for fertilising purposes. There were several such works in Pennsylvania and in the south.

Mr. R. C. WOODCOCK called attention to some very interesting results obtained by the direct application of this slag to the land in an exhaustive paper by Mr. Watson Smith, published in the Journal 10 years ago (1886, 464).

Mr. H. W. EDWARDS said that this fertiliser was readily assimilated merely on fine grinding. His information agreed with that of Mr. Woodcock.

Dr. G. M. STILLWELL said that it was a well-known fact that rock phosphates in fine division had been used to a large extent, but the difficulty was that they did not give the same quick return. The fertiliser manufacturers probably did not care to push the sale of these slags. The great object of manufactured fertilisers was to get quick results.

Dr. H. SCHWEITZER corroborated the statement that basic slag was largely used in Europe for fertilising purposes. It had only a small quantity of direct available phosphoric acid, and the large amount needed on the soil might sometimes be very injurious to plant life. If used judiciously, it was of great value, as experiments had proved.

Dr. G. M. STILLWELL added that these raw phosphates were more valuable as top-dressing for grass lands than for arable lands.

DISCUSSION ON PRESERVATION OF FRUIT.

Mr. H. W. EDWARDS stated that he was trying a few experiments on the shipping of fruit from Southern California, and as it seemed to him that the method at present employed was rather crude. Large cars are used, in which is placed more ice than fruit. He understood the freight on a car load of fruit, including ice, from California to New York, was something like 400 dols. He had tried putting the fruit in hermetically sealed cars with nitrogen and other gases, but he would be glad to have suggestions from members as to a more economical method and one which would not affect the flavour or delicate colour of the fruit.

Mr. MAXIMILIAN TOCH said that according to his experience the cheapest method was the use of sterilised air, for if certain germs were not excluded the fruit would begin to decay. He had preserved an apple for several months in air filtered through cotton and heated to a temperature of 300°.

Dr. H. SCHWEITZER stated that he had read a very interesting report on experiments which were carried out in France, and in which that very subject was reported (this Journal, 1895, 880). Grapes and other fruit were hung in a chamber in which was a dish containing a small quantity of alcohol. The fruit kept perfectly for some months without a trace of decomposition.

Dr. W. M. D. HORNE stated that he had had occasion to experiment on similar lines. A large shipper of olives asked his assistance in finding a method for preserving them. Olives are not picked until they are about ripe, and are then treated with salt water. After about three weeks they are very apt to spoil. It occurred to him that this was due to micro-organisms, so he carefully washed the salt water off, and then put the olives into sterilised water in sterilised bottles, with a small amount of antiseptic, 80 per cent. alcohol, boric acid, salicylic acid, and so on; but the olives became mouldy and spoiled. Successive sterilisations at low temperatures were more successful. The olives remained perfectly good in appearance until the water had all evaporated. He was inclined to think that this was a more promising method of preserving fruit than in salt water.

Dr. H. ENDERMANN stated that the method of preserving olives must be entirely different from that employed for food, which was always acid. In the case of the olives the treatment which they received rendered them alkaline. After the olives have been harvested they are laid in an alkaline solution and a good deal of tannin is extracted, and if the olives are examined it is found that the exterior of the olive has no alkaline reaction. It would be easier to preserve food, which is acid, than to preserve these alkaline foods.

Mr. E. H. GASE recommended the use of chloroform vapour.

Dr. H. SCHWEITZER stated that he had also had some correspondence on this subject of the preservation of olives. One of the largest growers in the country told him that first the olives were put into an alkaline liquid and after they were taken out they were treated with hydrochloric acid until a faint acid reaction was obtained.

Dr. H. ENDERMANN stated that this neutral reaction was only on the surface. Inside the olive the reaction was decidedly alkaline.

Mr. R. C. WOODCOCK said that a 1 per cent. solution of formaldehyde would keep any food perfectly, and that it was not improbable that it might be used with advantage for the preservation of fruit.

Dr. H. SCHWEITZER stated that its poisonous qualities would hinder its being used.

Mr. R. C. WOODCOCK said he thought not in such small quantities.

Mr. M. TOCH stated that he knew of no method which would yield more favourable results than that of sterilisation, and that fruit with an unbroken rind was impervious to germs.

PATENTS.

Acid-resisting Lining for Metallic Vessels, A New or Improved. R. Preston and T. Thornley, Bury. Eng. Pat. 21,477, Nov. 8, 1894.

This acid-resisting lining is formed by a mixture, in various proportions, of commercial asbestos, litharge, and a solution of silicate of soda or potash, or both, with or without the addition of either or both an insoluble silicate such as slag or sand, and a suitable insoluble sulphate such as sulphate of lime or of barium.

The following proportions have been found to give the best results in practice:—Asbestos, 20 parts; litharge, 10 parts; crushed slag, 70 parts. These ingredients are ground or mixed together, and a sufficient quantity of the silicate solution is added to form a paste, which, when applied to the walls of the vessel, adheres firmly thereto, dries quickly, and when dry, resists the action of ordinary mineral acids, and the effects of changes of temperature.—S. P. E.

Filtering of Liquids, Improvements in or relating to. A. J. Boulton, London. From A. Haacke, Celle, Germany. Eng. Pat. 1407, Jan. 21, 1895.

WHEN it is desired to clean the filtering medium or filter on which is deposited a coating of intercepted impurities, steam or air is applied in an opposite direction to that of the normal flow of the liquid through the filter, whereby the coating with the accumulated impurities is removed, without opening the filter casing. If steam be used, the filter is also sterilised.—R. S.

Heating, Evaporating, Distilling, and Condensing [principally Sugar Juices], Improvements in Apparatus for. F. H. Eydman, Weg Delft, Holland. Eng. Pat. 2723 Feb. 7, 1895.

In tubular heating, evaporating, distilling, and condensing apparatus as usually made, where the steam is outside, and the liquid passes through the tubes, there are two great disadvantages: (a) The accumulation of a film of condensed

* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to Sir Henry Reade Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

water on the outsides of the tubes, which film acts as a non-conductor of heat, and (b) The deposition of solid matter on the insides of the tubes. The former objection is obviated by arranging troughs, gutters, flat sheets, or channels below the tubes to collect and carry away condensed water; and to ensure that the condensed water is rapidly passed into the troughs, looped-shaped wires, thin flanges, or helical flanges are arranged on the tubes and dip into the troughs or the like. The latter objection is obviated by not allowing the liquid to evaporate within the tubes, but in a separate evaporating chamber, to which it is led by a tube provided with a self-acting valve. The liquid is forced through the tubes so as to completely fill them, and preferably travels at a speed of from 5 to 10 feet per second. To prevent priming and loss of material, a safety arrangement is employed in the evaporating chamber, consisting of layers of corrugated or coiled wire-cloth with meshes of different sizes, the corrugations in the various layers being arranged crosswise. This wire-cloth takes up the whole space above the boiling liquid to the vapour outlet. When no deposit is formed on evaporating, the apparatus may consist only of a tubular heater below and an evaporator with wire-cloth above. The arrangement can be used with multiple-effect apparatus, or with apparatus having the steam inside the tubes and the liquid outside; and is suitable for treating sugar juice, for surface condensers for steam engines, and for other purposes.—R. S.

Continuous Concentration of Liquids, Improvements in Methods and Apparatus for. S. M. Lillie, Philadelphia, U.S.A. Eng. Pat. 2824, Feb. 8, 1895.

THIS invention relates to apparatus in which the solution undergoing concentration has a practically continuous flow through the evaporating apparatus, the rate of flow varying with the rapidity with which the apparatus is working and with the degree of concentration desired. The rate of flow is regulated, and consequently the density of the concentrated solution, automatically, by means of the weight of the solution leaving the apparatus.

In the vacuum evaporating apparatus shown, the liquid enters by a tube *s*, provided with a hand valve *v*¹, and another valve *v*, automatically controlled by the float *f* in the chamber *F* and by connecting levers, the chamber being in communication with the bottom of the evaporating chamber *E*, so that as the level of liquid in this vessel rises or falls, the supply is cut off or increased, whereby the level is kept constant. The pan *E* is provided with two plates connected by tubes, and steam is admitted by the main *S* to the space between the plates surrounding the

tubes, while the vapour evolved passes away through the main *H*. The concentrated liquid is carried away through a tube *b*, and driven by the centrifugal pump *B* through the tube *c*, a balanced piston valve *V* regulating the flow. This valve is operated automatically by the rise and fall of a weighted flexible diaphragm *D* in the air-tight chamber *C*. The lower part of this chamber is connected by a tube to an upright tube *G*, which is open at the top to the space above the liquid in the pan *E*, while below, it is connected to the liquid outlet therefrom. The liquid rises in the tube *G*, and thus there is a greater or less tendency, according to its density, to raise the diaphragm, and thereby cut off or open the flow of liquid past the valve *V*. The upper part of the chamber *C* is connected to a vertical tube *i*, and water or counterpoise column *J*, the top of which is also in communication with the vapour space in the pan, and is provided with a gauge-glass *u*, marked for specific gravities. By means of the valves in the water connection *l* and in the drain pipe *m*, the column *J* may be filled to any height with water, and the level of the latter changed as required, whereby it will be seen that the density at which liquid can flow through the valve *V* will also be varied as desired. Various modifications are described and illustrated. The improvements may be applied to multiple as well as to single effect apparatus, and are also applicable to extractors or any apparatus in which solutions of substances are made, and in which the density of the resulting solution depends upon the rate at which it is run through the apparatus.—R. S.

Filtering Apparatus, Improvements in. A. Cabane, Adge-Hérault, France. Eng. Pat. 3,510, Feb. 18, 1895.

THESE improvements relate to filtering apparatus operating with or without pressure, and filtering without the use of felt or woven fabric, any quantity, from a centilitre to the largest quantities required, of any non-corrosive liquids, according as use is made of paper pulp, asbestos powder, or sheets of special filter paper. The apparatus consists of a cylindrical body closed by a cover making a hermetic joint, and having a central union for receiving either a pipe when filtering large quantities, or a funnel for small quantities. Below the cover is a perforated disc for distributing the liquid over either reversed cones of wire gauze, a double disc of perforated sheet metal and wire gauze, or a single disc of wire gauze.—R. S.

Drying Superphosphates and other Granular Materials, Improvements in and relating to Apparatus for. C. Zimmermann, Harburg; O. Rupert, A. Borgnis, C. von Merck, and E. Merck, Hamburg, Germany. Eng. Pat. 4429, March 1, 1895.

THE apparatus consists of a vertical chamber provided with a chimney at the top. The material to be dried is shot through a delivery pipe from a conveyor, on to the top inclined shelf of the shaft. It subsequently falls from shelf to shelf owing to the shake imparted to each by a rod which passes through the wall of the shaft and is actuated by a belt pulley and eccentric. The shelves are suspended by chains, the length of which is adjustable from outside the apparatus, so that the inclination of the shelf may be varied in order to accelerate or retard the duration of the drying process according to the nature of the material. The contents of each shelf can be viewed through doors situated on opposite sides of the shaft. At the bottom, the material falls on an inclined plane, and thus passes out of the chamber; the heating furnace is set laterally to facilitate this removal.—A. G. B.

Alarm-Thermometers, and Apparatus connected therewith, for the Automatic Transmission to a Distance of Signals indicating Deviations or Fluctuations of Temperature beyond Predetermined Limits, Improvements in. E. Tempel, Bremen, Germany. Eng. Pat. 13,647, July 16, 1895.

THE thermometer is made with a number of small platinum rods or pins passing through and sealed into the glass tube, namely, two passing into the bulb, and as many as required at any desired distance apart along the stem. These pins project inwardly into the bulb or into the mercury column,

and also outwardly beyond the outer surface of the glass. Two contacts are adjustably arranged upon the glass tube or upon a parallel insulating rod or bar, one for the upper or predetermined maximum temperature, and one for the lower or predetermined minimum temperature. It is necessary, therefore, to signal when the temperature falls below the minimum or rises above the maximum, and to do this the maximum contact and one of the bulb pins form an open circuit through a battery and bell, which circuit is closed when the mercury in the thermometer rises to make the maximum contact; while the minimum contact and the second of the bulb pins form a continuous or constant circuit through a bell working on the closed circuit system and battery; but when the temperature falls below the minimum, the relay armature in the bell leaves its position of rest and closes a circuit through the bell, the first-mentioned battery, and the two bulb pins, thereby sounding the signal.—R. S.

Bituminous Compound Material, Improvements in or appertaining to Apparatus for, and the Art of Treating, Working, and Handling Bituminous or Similar Compounds and Articles made therefrom. E. F. Badgley, A. R. Green, and A. Crockett, San Francisco (Cal.), U.S.A. Eng. Pat. 13,761, July 18, 1895.

The material employed by these patentees consists of various mixtures of asphaltum, bitumen, or petroleum residuum, with earthy and siliceous matter. These ingredients are heated together in a covered vessel and the lubricating and greasy constituents of the petroleum are distilled off. The still is provided with an agitator, and the operation is assisted by passing a blast of hot air through the mass under treatment.

More or less of the oily distillates are removed, according to the use to which the material is to be put; thus, for pavements, enough to prevent the compound from softening under solar heat; whilst for pipes and conduits, which are to be used under ground, more oils may be left in the mass.

When it is desired to make articles, such as "pile covering or armour, fence posts, panels, floor-tiles, slabs for various uses, flower-pots, electrical insulators, railway ties, &c., &c.," the mixture is allowed to flow over sheets of perforated paper, canvas, open-mesh cloth, wire-cloth, or sheet metal unwound from a reel on to a table, which is heated below by a furnace. The sheet is cut up as desired, either by a cutting wheel or by a plate working in a groove. Pipes are made by winding the sheet material one or more times round a core or mandrel.

The patentees' material is readily worked, as it does not stick to tools, &c., if these be hotter than itself, or if they be kept wet.

As soon as shape has been given to the articles under manufacture, they are cooled and permanently consolidated.

The patentees especially claim that greater uniformity of product is obtained by their method than by the older methods.—E. R. B.

Waste Oil or other Fluids, A New or Improved Apparatus for Filtering. T. Atkins and T. A. Harris, London. Eng. Pat. 14,431, July 30, 1895.

This apparatus consists of an outer vessel to contain the impure fluid, and an inner cylinder into which the filtered oil passes. Within the inner cylinder is a filter chamber, which can be screwed down from above into a socket containing a valve. The act of screwing down the filter chamber opens the valve and allows the unfiltered material to pass upwards through the filter and into the inner cylinder, whence it can be run off by means of a tap. The filter chamber contains the filtering material, such as charcoal, sand, &c., placed on perforated plates, "separated by spiral springs of graduated strengths, to enable the filtering material to be compressed to different densities by means of a winged nut and bolt or other suitable means." The whole filter chamber can be removed without disturbing the contents of either the inner or outer cylinders. In order to avoid disturbance of the unfiltered liquid which may be clarifying by precipitation, the unfiltered fluid is carried to the bottom by means of a tube. A layer of water placed below the impure oil facilitates the deposition of heavy particles.—C. A. M.

Evaporators for obtaining Common Salt, and for Analogous Purposes, Improvements in or relating to. T. Scott, Edinburgh. Eng. Pat. 15,197, Aug. 13, 1895.

This specification describes means for operating and cleansing evaporating vessels for concentrated saline solutions when worked by steam heat, by regular and frequent flushing with fresh or nearly fresh water, to dissolve and remove "salt-scale."

Specially constructed evaporators heated by close steam are described and claimed, and also the method of using hot distilled water from the secondary pans of salt evaporators for the purpose of dissolving rock salt to form brine.—R. S.

Vaporising Hydrocarbons or other Volatile Liquids, and Mixing the Vapour with Air for Use in Motors, Improvements in Apparatus for. B. W. Grist, Philadelphia, Penn., U.S.A. Eng. Pat. 16,096, Aug. 27, 1895.

See under 11., page 105.

II.—FUEL, GAS, AND LIGHT.

Coal Ash, Relation between Fusibility and Chemical Composition. E. Prost. Monit. Scient. 1895, 560—565.

THAT the ash be sufficiently refractory, is an important requirement in regard to coal intended for use as boiler fuel. The principal constituents of coal-ash, variations in which influence its fusibility, are— SiO_2 , Al_2O_3 , Fe_2O_3 , CaO , MgO . In a table, the molecular composition of a series of samples (Belgian) is given, together with notes regarding the behaviour of the latter when heated. Three approximately known test temperatures were employed: $1,160^\circ$, $1,350^\circ$ and $1,450^\circ$ — $1,500^\circ$ C.

From these results it is concluded that the degree of fusibility depends on the ratio of—(1) Al_2O_3 to SiO_2 , (2) Remaining bases (CaO , MgO , Fe_2O_3) to Al_2O_3 . In general, the melting point decreases as the percentages of SiO_2 and bases (excepting Al_2O_3) increase, and in this respect Fe_2O_3 has a greater influence than CaO . In presence of very large proportions of "bases"—which are *per se* highly refractory—the fusibility again decreases.

—H. T. P.

Petroleum Oils, The Quality of. R. Kissling. Zeits. angew. Chem. 1895, 563.

A CIRCULAR has recently been issued by Messrs. Dirks and Möllmann, Osnabrück, embodying the results of tests of illuminating petroleum made by B. Kohlmann during the last 12 years, in which it is sought to substantiate the statement that there has been a steady depreciation in the quality of these oils supplied to the German market. The tests, however, as pointed out in the present communication, are limited to "flash points," upon which it is contended there is no public opinion to substantiate. The following table of Kohlmann's results, rearranged from the original, shows that he fails even to establish a steady lowering of the flash point:—

Percentage of Oils with Flash Point under 21°	Year.	Percentage of Oils with Flash Points between 21 and 26°	Year.
6.0	1886	95.4	1894
5.1	1883	93.1	1884
4.6	1892	95.0	1885
3.7	1890	94.7	1893
2.5	1885	91.5	1891
1.4	1888	91.3	1899
1.1	1890	93.0	1889
0.5	1881	88.6	1892
0.5	1887	87.9	1886
0.0	1889	86.9	1883
0.0	1891	83.8	1887
0.0	1893	80.0	1888

Kohlmann's proposal to raise the legal minimum from 21° , as at present, to 37.5° , which is stated to be the Austrian legal minimum, is adversely criticised.—C. F. C.

PATENTS.

Water-Gas, Improvements in Apparatus for Generating and Carburetting. W. A. Forinness, Manchester. Eng. Pat. 14,885, Aug. 3, 1894.

The generator has a hollow cylindrical conical-topped base of cast-iron, the cylindrical walls of which are perforated.

The blast (with steam) is admitted to the interior of the base, and is heated by impinging against the lower side of the conical top, upon the upper side of which the mass of hot fuel rests. It issues through the perforations in the wall, into an annular flue surrounding the base, and thence passes up through the mass of fuel.

The carburettor consists of a cast-iron cylinder set in an annular flue, the top of which communicates with the generator, and into which the oil spray for enriching is injected. The iron cylinder has an exit pipe above, and at the bottom, is open to the flue surrounding it.

It is filled with a number of perforated grids, which store the heat required for "fixing" the enriching vapour as it passes, along with the water-gas, through them.

As the producer-gas passes up through these grids, it is completely burnt by an air blast admitted at the lower part of the carburettor. The mode of working is that usually followed.—R. B. P.

Carbides and Illuminating Gas derived therefrom, Improvements in the Production of Metallic. G. B. Ellis, London. From T. L. Willson, New York, U.S.A. Eng. Pat. 16,342, Aug. 27, 1894.

PULVERULENT lime and coke, or coal, are mixed in the proportions of 9 to 6 and heated in an electric furnace consisting of a carbon hearth or crucible, which forms one electrode, and an upright carbon pencil forming the other. Under the intense heat obtainable, calcium carbide is formed, which solidifies in crystalline masses, and on being brought in contact with water, generates acetylene. The calcium carbide produced in this manner is stated to be distinguished from that hitherto produced by its being in the form of a crystalline mass instead of being amorphous and incapable of aggregation into a solid mass, and also by its "almost complete purity." Each pound of carbide will produce 5.8 cb. ft. of acetylene (at atmospheric pressure).

—R. B. P.

Carbides, Improved Metallic, applicable for Use in the Production of Acetylene, and Means of producing the same. T. L. Willson, New York, U.S.A. Eng. Pat. 16,705, Sept. 1, 1894.

The subject-matter of this patent appears to be identical with Eng. Pat. 16,342 (see foregoing), but the third claim is modified.—R. B. P.

Gas [Acetylene] for Illumination, Heating, and other Purposes, and in Apparatus therefor, Improvements in the Manufacture, Distribution, and Use of. T. L. Willson, New York, U.S.A. Eng. Pat. 21,222, Nov. 5, 1894.

This invention relates to the general utilisation of acetylene gas in the place of ordinary coal-gas.

The production of the gas is effected by bringing a suitable metallic carbide in contact with water, and the gas may be mixed with a suitable quantity of air to cause it to burn with a clear flame. The following points, amongst others, are claimed. Distributing the gas under high pressure, and a method of automatically adjusting the rate of production to that of the consumption.—R. B. P.

Calcium Carbide, Improvements in Apparatus for Decomposing. H. Gabe, Copenhagen, Denmark. Eng. Pat. 17,746, Sept. 23, 1895.

The patentee's apparatus is shown in central vertical section in the figure, where *d* is a gas-bell, to the crown of which two or more charge-chambers, *g g*, are attached.

The charge-holders, *k k*, are cylindrical vessels with perforated walls, and contain layers of calcium carbide separated by discs of waterproof material.

In using the apparatus, the gland *n* is slackened and the rod *m* depressed so far that the lowermost layer of calcium carbide is immersed in the water; acetylene is now evolved, and the bell and its attached structures rise. If *c* be opened, the gas escapes by the apertures *f f* into *e*, and thence, by *b*, reaches *o*, where it deposits any water carried over; *q* is a filter. The layers of carbide may be successively brought into contact with the water, by manipulating the gland, and, when the charge-holder is exhausted, another may be brought into use.

The above apparatus is intended for domestic use; for larger uses, the same structure of charge-holder is employed, but it is now suspended in a fixed position from the interior of a bell, which is kept immersed in water. The water inside this bell, according to the amount of acetylene

generated, is more or less displaced. There are gas exits, both from the top and from near the bottom of the bell, the latter conducting to a holder, and being for use in the event of the charge retaining water and so continuing the generation of acetylene, at a time when none, or a less quantity of acetylene, is being removed direct from the bell, for use.

—E. R. B.

Acetylene, Automatic Gas-generating Lamp. C. Kaestner, Halle-on-Saale, Germany. Eng. Pat. 18,824, Oct. 8, 1895.

This lamp consists of an upper vessel containing water, attached to a lower one containing calcium carbide. The connecting piece, joining the two vessels, contains an elbow or bent pipe in which is a cock and a non-return valve. This pipe delivers the water to a felt filter; underneath which is a plate, with a single funnel-shaped downward extension. The aperture of the funnel "is made of a size to

correspond with the consumption of gas by the lamp, and in such a manner that only a single drop can form at this place." The acetylene formed by the reaction of the water upon the calcium carbide escapes to the burner by a pipe also provided with a cock. To extinguish the lamp the water is first turned off and then the gas cock.

To prevent the flame from smoking, the gas is made to escape at the burner through "extremely fine holes."

—E. R. B.

Gas, Manufacture of [Petroleum], and Apparatus therefor, Improvements relating to the. J. M. Bosselaar and J. F. M. van der Elshout, Brussels. Eng. Pat. 23,278, Nov. 30, 1894.

THE patentees especially aim at obtaining a relatively very perfect vaporisation of the petroleum immediately upon its introduction to a retort, heated to a "sombre red heat" (800—900° C.). It is, according to them, "not sufficient for the atmosphere merely of the retort to have this temperature; it is necessary that there shall be contact between the petroleum and a suitably heated wall." If the petroleum arrive in the heating chamber in a liquid state at all, it must be drop by drop, or, however thin the wall may be, there will be local lowering of its temperature, and vaporisation of an improper kind will result. Much of such vapours so produced will not be dissociated upon their subsequent contact with the hot walls of the retort, but will condense as soon as they are brought to a lower temperature.

The inventors describe apparatus suitable both for industrial and for domestic installations. The latter has the shape of a doubly-convex lens, and is contained by a protective vessel of like shape. The nozzles of two or more Bunsen burners penetrate the periphery of the outer vessel (the apparatus is disposed with its longest radii in a horizontal plane), and discharge their flames upon the inner vessel, so that this latter is entirely enveloped in flame, and its temperature is raised thereby to the desired red heat. Drop by drop, petroleum is now allowed to fall into the interior of the inner vessel, the orifices of the tubes admitting the petroleum being provided with conical plugs attached to rods passing down the tubes, which rods may be regulated by manipulating screws suitably arranged.

The industrial apparatus consists of two retorts communicating with each other at the end remote from the feed and the gas take-off; the retorts are entirely enclosed in a furnace.—E. R. B.

Gas Generators, Improvements in Oil-feeding Apparatus for. O. N. Gulllin, Fort Wayne, U.S.A. Eng. Pat. 23,455, Dec. 3, 1894.

THE arrangement patented is for automatically controlling the quantity of oil used for enriching water-gas. A meter is used to measure the quantity of oil employed, a steam-pump for forcing the oil into the superheater, and an automatic governor on the steam-inlet of the pump, by the action of which a uniform pressure is maintained in the oil-delivery pipe.—R. B. P.

Liquid Hydrocarbons, and the Production therefrom of Gas and Valuable By-Products, Improvements in and Apparatus for the Treatment of. P. Dvorkovitz, London. Eng. Pat. 23,671, Dec. 5, 1894.

ACCORDING to this invention, by causing petroleum (or other liquid hydrocarbon) to flow through an extensive series of retorts, in which it is progressively subjected to temperatures ranging from 300° C., or even as low, in some cases, "as 150° F.," up to 1,000° C. (dull red heat), it is possible to obtain from it not only gas, but also "valuable liquid by-products, which are in part of a novel character, consisting as they are said to do, of unsaturated hydrocarbons of hitherto unknown series, and containing also benzol, toluol, xylol, and the like." No coke and but very little pitch is produced.

The retorts are arranged in inversely-inclined positions, the lower end of each retort communicating with that below it by connecting-pipes.

The retorts are contained in a chamber connected with the furnace, the chamber being so divided up into flues that the heated products of combustion from the furnace raise

the lowest retorts to temperatures not exceeding 1,000° C., whilst the uppermost retorts in the bench may have temperatures as low as 300° C. These retorts are of great width and small depth.

The pipes which traverse the upper part of the chamber conduct the, now warmed, hydrocarbon to the first retort. The gas formed and the liquid hydrocarbon products pass from retort to retort and finally escape by a down-pipe from the lowest retort in the bench (nearest the furnace) into a main, where any heavy condensed matter collects. A rising pipe conducts the gases from the main to the condensers, &c., where the unsaturated hydrocarbons are deposited, the permanent gas passing on to the gasometer.—E. R. B.

Gas from Carbonaceous Matter, Improvements in Apparatus or Furnaces for Producing. C. W. Pinkney, Smethwick. Eng. Pat. 2017, Jan. 29, 1895.

THIS patentee claims, for gas-producing furnaces, a vertical 3-zoned fuel chamber, such that into its upper part (or zone), P P, raw fuel may be fed by the hopper T, and incandescent fuel exist in its lower part F, while at its intermediate part or zone R the fuel is acted upon by

steam (superheated or otherwise) and air. To carry out this latter process, the intermediate part is provided with vertical and, generally, inclined grate bars C C, and the

whole of this part of the furnace is surrounded by the annular chamber D D, to which air and steam are admitted by Q Q.

The gas exit is at G, the course of the gas having been downwards through the fuel in F. Clinker may be removed at the doors H H, while ash and clinker, when the furnace is working continuously, falls into the water-seal chamber M, which closes the bottom of the furnace. Any ash produced in the middle zone R of the furnace, may be removed at the door S. N N are stirring holes.—E. R. B.

Line-Light, Improved Ether Saturator for the Production of. W. Houldershaw, Liversedge, York. Eng. Pat. 2195, Jan. 31, 1895.

This invention relates to a mechanical stand for the usual gas and spirit jets; to a special form of diffusion chamber having fluted gas passages to distribute the gas uniformly through the saturated material; to an arrangement of spiral tubes for splitting up and vaporising the ether particles; and to various other points connected with optical lanterns in which a burning jet of oxygen and ether (or petroleum spirit) vapour is used in conjunction with a cylinder of lime.—R. B. P.

Mingling Gas or Air and "Acetylene Gas" or other Enriching Gas for Illuminating Purposes, Improved Methods of and Apparatus for. H. H. Lake, London. From E. N. Dickerson, New York, U.S.A. Eng. Pat. 11,848A, June 18, 1895.

THE present invention mostly concerns a novel means of remedying a certain difficulty, the existence of which is now announced, according to the patentee, for the first time. It is stated that, unlike other enrichers, acetylene "will disappear, in part at least, if it remain in contact with water-gas for a considerable time; as, for instance, during the period in which gas is stored in gasworks until its delivery to the consumer." The gases must therefore be mixed at the place of consumption.

The apparatus for mixing the gases consists of three ordinary bell gas-holders of like structure, two of which contain respectively acetylene and water-gas (or air), and communicate with the third, which is thus the mixing chamber. By employing, on the tubes delivering acetylene and water-gas respectively, cocks the ports of which have known areas, and by keeping the pressures under control, definite proportions of the gases may be automatically delivered into the mixing chamber.

For the proper burning of acetylene in ordinary burners, "either equal parts of acetylene and air, or proportions varying from 40—50 of air, to 60—50 of acetylene," should be employed.

The patentee also describes means for the mixing of the gases under high pressure, whereby the expanding power of one of the gases is utilised to accomplish the compression of the other.—E. R. B.

Burners and Mantles for Incandescence Gas Lighting. Improvements in. A. Taylor and W. S. Taylor, both of Glasgow. Eng. Pat. 1577, Jan. 23, 1895.

THE burner is constructed so that it can be used as an ordinary burner in the event of the mantle breaking. According to one modification, the mantle is made from a suitable fabric which is first dipped in a weak solution of hydrobromic acid 40 per cent., ammonium bichromate 40 per cent., uranium acetate 10 per cent., and potash alum 10 per cent., and then in a strong solution of calcium carbonate, or in a solution containing 60 per cent. of calcium carbonate and 40 per cent. of magnesium carbonate. The supporting fabric is then burnt away in the usual manner. Phosphoric acid, acetic acid, or ammonium chloride may be substituted for the hydrobromic acid.

—R. B. P.

Incandescent Gas Lamps, Improvements in. A. Farkas, Paris. Eng. Pat. 14,404, July 29, 1895.

THE improvements claimed are:—(a) A special form of burner in which the air and gas become thoroughly mixed before ignition; (b) A cone of fireproof material situated

inside the mantle, the object of which is to increase the temperature of the air and gas, and, by acting as a reflector, the amount of light given off; (c) A circular groove surrounding the burner to receive the lower edge of the mantle and protect it from breakage; (d) A method of securing the chimney so that it is not affected by shocks or vibrations; (e) A central draught which makes it possible to add a larger quantity of air to the gas in order to raise the temperature of the flame, at the same time reducing the consumption of gas.—R. B. P.

Incandescent Lamps for Vaporised Liquid Fuel, Improvements in. A. Baermann, Berlin, Germany. Eng. Pat. 16,343, Aug. 31, 1895.

THE lamp has an ordinary burner, incandescing body, and chimney, the latter being, however, considerably shorter than usual. The combustible liquid is fed from a suitable closed reservoir by the capillary action of a tube filled with an absorbent material, into a vaporising chamber placed over the chimney, and becomes converted into vapour by the heat of the lamp. The vapour then passes through another tube to the burner. The chief claim is the utilisation of the heat from the lamp itself, instead of using a separate flame to vaporise the liquid.—R. B. P.

Incandescent Gas Lamps, Improvements in. W. L. Voelker, Elizabeth, N.J., U.S.A. Eng. Pat. 17,795, Sept. 24, 1895.

A FRAME, or carrier, made of porcelain or of a "porcelainous" compound, is used to support the incandescing oxides.

The frame is constructed of threads made from a mixture of finely-powdered kaolin, quartz, felspar, and sugar syrup, by squirting through a die.

The hood is then dried and baked at a high temperature, dipped in a suitable solution, and finally oxidised.—R. B. P.

Vaporising Hydrocarbons or other Volatile Liquids, and Mixing the Vapour with Air for Use in Motors, Improvements in Apparatus for. B. W. Grist, Philadelphia, Penn., U.S.A. Eng. Pat. 16,096, Aug. 27, 1895.

THE inventor's apparatus, which is intended to be interposed in the path of the incurrent air of gas-motors, is represented, in vertical section, in the figure.

It consists essentially of a cone E, which is perforated with numerous minute apertures, and which is kept wet by hydrocarbon dropping from G. The inflowing air arriving by a, traverses the minute apertures of the cone, becomes

carburetted, is mixed with further air (arriving by the apertures *t t*), and passes on to the cylinder of the gas-engine. F is a deflector, preventing the inflowing air from merely blowing through the apex of the cone. *p* is an annular chamber communicating with the exterior by a

series of apertures *l l*, and with the interior by the passages and apertures *l l*. It conducts the supplementary air of the charge; the amount of this latter being regulated by an annular valve, *a*, which is provided with ports or passages, *n n*, registering with the passages *l l*.

This valve, as also *D*—that regulating the main air supply—is opened by the induction stroke of the piston of the gas-engine, and the two valves close automatically, the former by the springs *s s*, the latter by gravity. Any excess of hydrocarbon falling through the cone is caught in the chamber *c*.—E. R. B.

Gas Generators, Improvements in Oil-atomising and Carburetting Apparatus for. O. N. Gublin, Fort Wayne, U.S.A. Eng. Pat. 16,927, Sept. 10, 1895.

THIS is an injector for feeding finely-divided or "atomised" hydrocarbon oil into a water-gas carburetting apparatus.

The injector consists of a tube terminating in a conical end, in which is situated the exit orifice. A plug, with a conical end forming a valve for wholly or partially closing the exit orifice, is mounted on a screwed spindle, by adjusting which, the amount of oil injected can be controlled. Projecting lugs on the plug, guide it in the body of the injector, and at the same time break up the stream of oil into fine particles.

From the shape of the lowest set of lugs, a "whirling" motion is given to the particles as they leave the injector.

—R. B. P.

Fuels, An Improved Method of and Apparatus for Vaporising Solid and Liquid, and Utilising the Vapour for Heating Purposes. J. E. Pfeil, Vienna. Eng. Pat. 17,268, Sept. 16, 1895.

THIS invention relates to the production of smokeless flames of relatively high temperature, from petroleum, rape-oil, olive-oil, &c., or from stearin, paraffin wax, &c., while the "heating purposes" contemplated include the rendering incandescent of a mantle.

According to the patentee, the liquid or molten fuel is sucked up by a solid wick of relatively large diameter, which is surrounded at its upper end by an annular flame. The heat emitted by this flame vaporises the fuel brought up by the inner part of the wick. The fuel vapours so formed enter a chamber, whence after being mixed with a suitable quantity of air, they can escape through a grating at the top, and, upon ignition, yield a colourless flame.

The apparatus, by means of which the vaporisation of one part of the liquid fuel by the combustion of the other part is accomplished, is illustrated and described.

In the case where the colourless flame is used to render incandescent a mantle, the patentee uses a chimney, as usual; and, by means of a metal cap, causes most of the air which enters the chimney to take a definite path between the edge of the metal cap and the burner, and by this means he secures a more active combustion in the outer portion

of the flame; moreover, the shape of the flame becomes the more constant. Both these causes conduce to a higher degree of incandescence.—E. R. B.

Hydrocarbon Liquids, Improvements in Gasifying and Distilling. S. Pitt, Sutton. From La Société Internationale des procédés Adolphe Seigle, Levallois-Perret, France. Eng. Pat. 19,036, Oct. 10, 1895.

By means of a spray producer, or otherwise, an "emulsion of water and hydrocarbon" is produced, and this is led through a metallic worm heated in any suitable manner. Here, is successively effected the reduction of the water by the carbon resulting from the dissociation of certain of the hydrocarbons, and the carburation of the poor gas so produced, by other of the hydrocarbons and by certain stable hydrocarbons produced at the moment when the others were dissociated. By introducing carbon, or coke, into part of the worm, the quantity of poor gas may be augmented.

"Any apparatus suitable to the object in view, may be employed."

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Nitrogen and the Nitrogen Products derived from Coal. Knublauch. J. f. Gasbeleuchtung, 33, 753—758 and 769—773.

THE author describes in detail the results of experiments and observations made during a number of years at the Cologne gasworks, and subsequently in his laboratory.

The amount of nitrogen is very variable in different coals and even in the same kind. There is from 1.3 to 1.6 per cent. in Westphalian coal. The proportion converted into valuable compounds, however, forms only from 0.2 to 0.25 of the weight of this coal. The amount of coal distilled daily in gasworks and coke ovens over the whole globe is estimated at 1,000,000 tons, corresponding to 10,000 tons of ammonium sulphate, taking the nitrogen recovered as ammonia at 0.2 per cent. of the coal. The coal used at Cologne introduces annually into the gas retorts alone about 1,000 tons of nitrogen, of which 200 tons are recovered as ammonia and cyanogen, and these calculated as sulphate may be valued at 12,500*l*. Experiments showed that the ammonia completely extracted from the gas in the gas liquor yielded only from 9.74 to 10.15 lb. of ammonium sulphate per ton of coal, corresponding to a percentage of nitrogen in the coal of approximately 0.2 only. Estimations of the nitrogen in the coal showed seven to eight times that quantity. Attempts to convert more nitrogen into ammonia were so far successful, but, on the other hand, disadvantages accrued, and the new processes were abandoned. As an illustration, the author refers to the addition

of lime to coal before distillation (this Journal, 1887, 503), and the passage of steam over the incandescent fuel.

Of the balance of the nitrogen, a very small quantity occurs as cyanogen in the gas and as nitrogenous bases in the tar, but by far the largest quantity is found in the gas and the coke. Having devised an apparatus for carbonising coal in the laboratory, it was found that the yield of ammonia, generally possible, could be determined for different coals, and the variations made were dependent only on the choice of the coal. It was further proved that the percentage of nitrogen contained in the coal and its distribution among the various products, is by no means proportional. The yield of ammonia may, for instance, be much greater from a coal containing a small percentage of nitrogen than from one very rich in nitrogen. The same remark applies to the other nitrogen products. These variations are frequently very great with coal of different origin, and often slight with the same kind, though even then they are at times very considerable.

The same question has been investigated by Foster for English coals, whilst subsequently Schilling also made some experiments with various kinds (this Journal, 1887, 652), the yield of ammonia found being confirmed in the three series of observations. The author has made a large number of distillations of various kinds of coal to ascertain the yield in the various products.

The average yield of gas, coke, tar, and ammonium sulphate from 15 different sources is shown in the table on preceding page.

The distribution of the nitrogen among the different products is shown by the results given in the following table:—

	Percentage of Nitrogen on the Coal.		Percentage of Nitrogen on Total Nitrogen.

With regard to the quantity of cyanogen formed in the retorts, numerous experiments carried out at various times with Westphalian coal, indicate that 74 to 79 grains of hydrocyanic acid per 100 cb. ft. are present in the gas, or about 0.15 per cent. by volume of the acid in the state of vapour. This corresponds to from 2.9 to 3.1 lb. of potassium ferrocyanide per ton of coal. It is generally less at the coke ovens. The nitrogen of the cyanogen therefore amounts to only 0.02 to 0.03 per cent. on the coal, corresponding to 1.8 per cent. of the total nitrogen of the coal.

The following is the average composition of crude gas from Westphalian coal, expressed in per cent. by volume:—Hydrogen, 50.00; methane, 31.00; carbonic oxide, 9.00; ethylene, 2.50; benzene, 1.25; carbonic anhydride, 2.00; hydrogen sulphide, 0.75; nitrogen, 2.25; ammonia, 1.10; hydrocyanic acid, 0.15; sulphur compounds (other than hydrogen sulphide), carbon bisulphide, &c., about 0.01.

In summarising the results of these experiments the following conclusions are drawn, based on Westphalian coal:—(1.) About 50 per cent. of the nitrogen remains in the coke, and is only of interest inasmuch as an increase in its amount results in a corresponding decrease in free nitrogen present in the gas. (2.) About 30 per cent. of nitrogen is contained in the gas, and must be considered injurious as reducing the illuminating power. (3.) From 12 to 14 per cent. is converted into ammonia, corresponding to 10.55 lb. of ammonium sulphate per ton of coal. (4.) Not quite 2 per cent. (0.027 per cent. on the coal) combines with carbon and hydrogen to form hydrocyanic acid, corresponding to 1.42 lb. of potassium ferrocyanide per ton of

coal. Of this quantity, at least two-thirds should be recovered from the oxide. (5.) Finally in the tar as nitrogen bases, there is about $1\frac{1}{2}$ per cent. (equal to 0.02 per cent. of the coal). (6.) Only 0.2 to 0.25 per cent. of the nitrogen of the coal forms products of marketable value; but the quantities dealt with being large, it is nevertheless possible to obtain a revenue of 14l. per million cubic feet of gas.—D. B.

Anthracene, Formation of, in the Distillation of Crude Carbohc Acid. H. Köhler. Zeits. f. angew. Chem. 1895, 16, 476—477.

IN a recent discussion on the condensation products derived from the distillation of phenoloid aluminium compounds, Zmerzlikar asserted that their study promised the dissipation of an erroneous theory, adduced by Schulze some time ago, relating to the formation of anthracene.

The author states that, although Schulze based his views as to the formation of coal-tar on the observation that the phenols separated from anthracene oil, when subjected to distillation, yield liquid hydrocarbons with liberation of water, no reference as to the production of anthracene has ever been made by this chemist. The author, however, on one occasion, in working up the high boiling portions of crude carbohc acid, obtained anthracene in the distillate, which was carefully examined by Luck's method and found to contain 35 per cent. of pure anthracene. It is, he thinks, difficult to confuse the "pyrocresols" observed by Zmerzlikar, with anthraquinone, and to imagine that these substances could have yielded anthraquinone on oxidation with chromic acid.—D. B.

Naphtha, Crimean. Properties of. A. L. Potylitzin and B. Bernstein. J. Russ. Chem. Soc. 27, 279—282.

ABOUT 800 tons of naphtha (crude petroleum) were produced in the Crimea in 1891, chiefly at Chengelek, where the borings attain a depth of 400 metres. A specimen from that source was of a dark brown colour with greenish fluorescence, and had the sp. gr. 0.888 at 17°.—J. W.

Mineral Oil Refining, Theory and Practice of. R. Zoloziecki. Chem. Rev. Fett u. Harz Ind. 1895, [30], 1—4.

THE influence of temperature on the acid purification process has been already discussed by the author (this Journal, 1895, 563), who now points out that his remarks were intended to apply only to actual distillates, and not to decomposition products. As the heavy oils must be considered as belonging to the latter category, the limitation of the range of temperature to about 0° C. is not applicable to them, but in any case it is desirable to keep the temperature as low as is possible consistent with the attainment of the necessary fluidity to ensure thorough intermixing of oil and acid. The most favourable temperature, therefore, depends on the viscosity of the oil, and will require to be separately ascertained for each particular quality. For oils of equal viscosity it is probable that the temperatures will coincide.

Concerning the influence of light on asphalt, recorded by Windisch (this Journal, 1895, 1039), the author agrees that the susceptibility to light is probably in direct relation to the amount of sulphur present in combination, but considers that, as the effect of light on these sulphur compounds in the acid tar is to render them insoluble, some other explanation of the deepened colour of the oil must be sought. In his view—in support of which he quotes the results obtained by Ostrejko and Charitschkow (this Journal, 1896, 24, 26)—the effect is due to the oxidation of the acid tar, a process furthered by the action of light on the oil, and the simultaneous solution of some of the resulting asphalt products.—C. S.

IV.—COLOURING MATTERS AND DYES.

Parafuchsine, New Synthesis of, and of its mono-, di-, tri-, and tetra-alkylated Derivatives. M. Prud'homme. Comptes rend. 121, 1895, 891—893.

THE careful reduction of nitrobenzene gives phenylhydroxylamine, which is converted by mineral acids into *p*-amido-phenol. The same reaction can be carried out with the *p*-nitrodiamidodiphenylmethanes, although the position para to the nitro group is occupied by the central carbon atom. When dissolved in dilute hydrochloric acid and treated in the cold with zinc dust, the following transformation takes place:— $\text{O}_2\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}_2\text{A}_2$ (nitro compound); $\text{HO} \cdot \text{HN} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}_2\text{A}_2$ (hydroxylamine); where A represents C_6H_4 , NH_2 , NR , R being an alkyl radicle. Under the action of hydrochloric acid at a moderate temperature, a reaction takes place between the hydroxyl group and the hydrogen attached to the methane carbon, forming a derivative of a tri-amido-carbinol, which is converted into a colouring matter by the interchange of the hydroxyl group for an acid radicle:— $\text{H}_2\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CA}_2\text{OH}$ (colour base); $\text{H}_2\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CA}_2\text{Cl}$ (colouring matter). The addition of sodium acetate precipitates the nitro or amido leuco bases, and after filtration the zinc is eliminated by caustic soda, the base of the colouring matter crystallising from alcohol in a state of purity. The method has been applied for the synthesis of parafuchsine and its mono-, di-, tri-, and tetra-alkyl derivatives. The *p*-nitro-methanes from which *p*-fuchsine and its tetra-alkylated derivative are produced, are obtained by condensing one molecule of *p*-nitro-benzaldehyde with two molecules of aniline or of a dialkylated aniline. In a similar manner the mono- and tri-alkylated compounds are formed by condensing alkylated *p*-nitrodiamidodiphenylhydrol with aniline or a dialkylated aniline. In the case of the dialkylated fuchsines the two alkyl groups may be present in the same or in different benzene nuclei. Those in the former class are produced by condensing one molecule of *p*-nitrobenzaldehyde with two molecules of a monalkylated aniline, whilst the latter are obtained by condensing dialkylated *p*-nitro-amidodiphenylhydrol with aniline. The shades produced by this series of fuchsines approach the violet end of the spectrum in proportion to the number of alkyl groups present, and it is noteworthy that two alcohol radicles in two different benzene nuclei produce a more violet shade than when they are both contained in a single nucleus.—T. A. L.

New Safranines. G. F. Jaubert. Comptes rend. 121, 1895, 947—948.

THE simplest safranine hitherto known is Witt's phenosafranine, which is a diamidophenazine phenylated in the azine ring. The author describes several new safranines containing other radicles, such as methyl, ethyl, α - and β -naphthyl, in place of the phenyl in phenosafranine, which he designates metho-, etho-, α - and β -naphthosafranines.

Methosafranine.—By oxidising a mixture of *p*-phenylene diamine and methyl-*m*-phenylene diamine, mono-methyl-phenylene red is obtained in place of the desired safranine, since the position para to the substituted amido group in the *m*-phenylene diamine is unoccupied. By using the mono-methyl derivative of *m*-cresylene diamine a good yield of metho-2-tolu-safranine is obtained, having the following constitution:—

This product dyes mordanted cotton ponceau - red, dissolves in water with a red colour and yellow fluorescence, whilst in hydrochloric acid it dissolves with a blue and in sulphuric acid with a green colour. Nitrous acid gives a diazo derivative.

Etho-2-tolu safranine is obtained in a similar manner from ethyl-*m*-cresylene diamine. Etho-safranol is formed by reacting with nitroso-phenol on ethyl-*m*-amidophenol, and in the same way the α - and β -naphthosafranols are produced from nitrosophenol and *m*-hydroxy-phenyl- α - and β -naphthylamine. A sulphonic acid of phenosafranol can be obtained by using a sulphonated *m*-hydroxydiphenylamine.—T. A. L.

Researches on Tertiary Benzenoid Amines. I. Derivatives of Dimethylaniline. Clara de Brereton Evans, B.Sc. Proc. Chem. Soc. 1896, [158], 235.

It is now established in the case of primary and secondary benzenoid amines, that the production of derivatives containing a substituent in the hydrocarbon nucleus is often preceded by that of the corresponding derivative in which the substituent is present in the amido-group; and inasmuch as compounds of the latter readily pass over into those of the former class, it is not improbable that their formation is a necessary step in that of many derivatives of benzenoid amines. As it is impossible, however, that similar derivatives should be formed from tertiary amines, the behaviour of these is of interest as throwing light on the influence which nitrogen itself exercises; and that this may be altogether different from that of nitrogen associated with hydrogen is clear from a comparison of benzenoid amines with *azophenes* (compare Proc. Chem. Soc. 1892, 128) such as pyridine and quinoline, as these latter manifest a comparative indifference towards agents generally which is quite remarkable.

The experiments to be described have brought to light the fact that tertiary benzenoid amines manifest a somewhat similar indifference.

Dimethylaniline is readily sulphonated by means of chlorosulphonic acid, yielding only the *para*-acid; it is somewhat less readily, but yet easily sulphonated by means of a single molecular proportion of ordinary sulphuric acid, but if a larger proportion of acid be used, the action takes place less readily, sulphonation being incomplete at the end of twelve hours at 180° when 5 molecular proportions of acid are used, although it is complete within five hours when a single proportion is taken. Practically nothing but the *para*-acid is formed. To procure the *meta*-acid, it would seem that it is necessary to use fuming sulphuric acid—a point of some interest in connection with the moot question as to the manner in which isomeric sulphonic acids are generated. The behaviour of diethylaniline is similar to that of dimethylaniline.

The behaviour of the *para*-acid towards bromine is remarkable. It first yields a *monobromo*-acid, and on further bromination a *perbromide*, readily and simply deprived of its bromine by exposure to air, by boiling with water, and in contact with ammonia, sulphurous acid, or potassium iodide. Under no condition, apparently, does it yield a *dibromosulpho*-acid or *tribromodimethylaniline*; in this respect its behaviour is most remarkable in comparison with that of ordinary sulphanilic acid, which is extremely sensitive to the action of bromine, being very readily converted into *tribromaniline*.

The *meta*-acid, in like manner, readily yields a *parabromo*-acid, identical with that obtained on sulphonating *parabromodimethylaniline*, and this is converted into a *dibromo*-acid by the further action of bromine. But all attempts to prepare a *tribromo*-acid corresponding to that which is so readily obtained from *aniline*-*meta*-sulphonic acid, were unsuccessful. No *perbromide* is obtained from the *meta*-*bromo*-acids.

On nitration, *dimethylaniline*-*para*-sulphonic acid yields a mixture of *ortho*-*para*-*dinitro*-*dimethylaniline*, together with *ortho*-*nitro*-*para*-sulphonic acid, the latter being the chief product. The *meta*-sulphonic acid yields a *dinitrosulphonic* acid.

The behaviour of the *diethylaniline*-sulphonic acids is similar to those of *dimethylaniline*. The *perbromide*

derived from the bromoparasulphonic acid is better characterised even than that derived from the dimethylated acid.

2 : 1 β -Naphthylaminesulphonic Acid and the corresponding Chloronaphthalenesulphonic Acid. H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1896, [158], 238.

TOBIAS has recently shown (this Journal, 1894, 800) that the acid obtained by one of us (Armstrong, Ber. 15, 1882, 202) by the action of chlorosulphonic acid on β -naphthol at the ordinary temperature, is 2 : 1- β -naphtholsulphonic acid, and has described the amido-acid obtained by heating the hydroxy-acid with strong aqueous ammonia under pressure at 220°–230°.

This amido acid was converted by the Sandmeyer method into the corresponding 2 : 1- β -chloronaphthalenesulphonic acid, which has not hitherto been described, and is the 12th of the 14 isomerides which it is theoretically possible to isolate. The chloride, $\text{Cl} \cdot \text{C}_{10}\text{H}_6 \cdot \text{SO}_2\text{Cl}$, crystallises from a mixture of benzene and light petroleum in large, tabular forms, and from acetic acid in diamond-shaped scales melting at 76°: it yields an amide crystallising in slender needles melting at 153°, and on distillation with phosphorus pentachloride is converted into 1 : 2-dichloronaphthalene, melting at 35°.

On sulphonation with four times its weight of cold 20 per cent. anhydro-sulphuric acid, the 2 : 1- β -naphthylaminesulphonic acid is converted into the 2 : 1 : 4'- β -naphthylaminedisulphonic acid, previously described by the authors as the minor product of sulphonation of the Dahl 2 : 4'- β -naphthylaminesulphonic acid under similar conditions (this Journal, 1890, 800).

1 : 3- α -Naphthylaminesulphonic Acid and the corresponding Chloronaphthalenesulphonic Acid. H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1896, [158], 238–240.

IN the course of their study of the formation of isomeric naphthalene derivatives, the authors had occasion to attempt the repetition of Clève's work on the nitration of naphthalene- β -sulphonic acid, since of the three acids obtained by him in this way, one was stated to have the constitution—

the other two being the isomeric heteronuclear- α -nitro-acids. Whilst successful in obtaining two heteronuclear acids, of which they determined the constitution, they were unable to prepare the homonuclear compound by the nitration of potassium naphthalene- β -sulphonate (Proc. 1889, 17). Subsequently it came to their knowledge that the homonuclear acid also could not be detected in the product obtained on nitrating sodium naphthalene- β -sulphonate on the large scale. Moreover, Erdmann and Süvern have failed to obtain the corresponding chloride by nitrating naphthalene- β -sulphonic chloride (Annalen, 275, 252).

The authors record the fact that the so-called [7-] naphthylaminesulphonic acid which Clève prepared by reducing the homonuclear nitro-acid he obtained by nitrating sodium naphthalene- β -sulphonate (Ber. 19, 2179; 21, 3271) is identical with the 1 : 3- α -naphthylaminesulphonic acid of Kalle and Co.'s German Patent 64,979, prepared from α -naphthylamine-[ϵ]-disulphonic acid—which the authors have shown has the constitution—

(this Journal, 1890, 283)—by partially hydrolysing it with diluted sulphuric acid, and which, as Friedländer has recently shown, may also be obtained by partially reducing the said disulphonic acid with sodium amalgam (Ber. 28, 1951).

The experiments the authors have made with this disulphonic acid confirm Clève's statements as to its properties, and the derived 1 : 3- α -chloronaphthalenesulphonic acid, in every particular. The authors have been able to carry the identification of the acids a stage further, since they find that the dichloronaphthalene, melting at 61.5°—obtained from the chloronaphthalenesulphonic chloride melting at 106°—on sulphonation gives products characteristic of 1 : 3-dichloronaphthalene (Proc. Chem. Soc. 1890, 82), and not of the 1 : 2'-isomeride of about the same melting point with which it was for a while confused.

Tri-Derivatives of Naphthalene No. 15, Studies on the Constitution of. The Disulphonic Acids obtained by sulphonating 1 : 3- α -Naphthylamine and 1 : 3- α -Chloronaphthalene Sulphonic Acids. H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1896, [158], 240–241.

As already announced (this Journal, 1890, 284, 801, 802; Brit. Assoc. Report, 1893, 382, footnote), the authors are engaged on experiments having for their object the determination of the comparative influence exercised by the radicles Cl , OH , and NH_2 in naphthalene derivatives on the formation of disulphonic acids (this Journal, 1890, 800 *et seq.*). Progress was retarded so long as the characteristics of the reference compounds—the trichloronaphthalenes—were in doubt. The 14 theoretically possible isomerides are now known and characterised (Proc. Chem. Soc. 1895, 84), and, in view of the interest attaching to the 1 : 3- α -naphthylaminesulphonic acid, the authors think it well to put on record the results obtained on sulphonating it and the corresponding chloro-acid, so far as their experiments have gone.

From these results the authors say that, under the conditions described, the disulphonic acids obtained both from the 1 : 3- α -amido- and the 1 : 3- α -chloro-monosulphonic acids have a corresponding constitution expressed by the symbols—

PATENTS.

New Blue Colouring Matters for Dyeing and Printing, Improvements in the Production of. Read Holliday and Sons, Ltd., and R. Holliday, Ilkley, Leeds. Eng. Pat. 2504, Feb. 5, 1895.

ROSANILINE, when heated with *p*-phenylene diamine and aniline in presence of benzoic or other suitable organic acid, is converted into a soluble blue colouring matter, which, as hydrochloride, is suitable for dyeing and printing. In place of aniline, α - or β -naphthylamine may be used, and the shade may be varied by increasing the quantities of *p*-phenylene diamine and diluent employed. The solubility of the colour depends upon the amount of *p*-phenylene diamine used and also upon the temperature. About 100 lb. of rosaniline, 200 lb. of *p*-phenylene diamine, 400 lb. of aniline, and 5 lb. of benzoic acid, are heated at about 150° C. until a sample dissolved in alcohol and acetic acid and spotted on filter paper, gives the blue shade required. The melt is then cooled and sufficient hydrochloric acid added to render it soluble in hot water. From this solution, the colouring matter is salted out, when it is filter-pressed and dried; or the treatment may be repeated to remove any traces of amines. In order to obtain the dyestuff as concentrated as possible, the aqueous solution, free from amines, is precipitated with an alkali, the colour base being then filtered off and subsequently dissolved in the quantity of hydrochloric acid sufficient to render it soluble.—T. A. L.

Colouring Matters [Safranines], The Manufacture or Production of. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 2900, Feb. 9, 1895.

THESE safranines are prepared from alkylated *o*-toluidine, and give colouring matters which in some cases are equal

in brilliancy to the rhodamine dyestuffs. Any of the known processes for the production of safranines may be employed, the following being a typical example:—A solution of 18·6 kilos. of nitrosomethyl-*o*-toluidine hydrochloride in 500 litres of water is converted by means of zinc-dust and hydrochloric acid into *p*-amido-methyl-*o*-toluidine, and, after neutralisation, 15·8 kilos. of methyl-*o*-toluidine hydrochloride dissolved in water are added, the whole being oxidised in the cold with 20 grms. of potassium bichromate as a 5 per cent. solution, with constant agitation. When the indamine is completely formed, 14·5 kilos. of *o*-toluidine hydrochloride dissolved in water are added, and the solution is heated until the original bluish-green colour has become red. A further quantity of 20 kilos. of potassium bichromate is then added, and the heating is continued until the formation of the colouring matter is complete. After filtering, the residue is extracted with water, and the filtrate from this operation having been mixed with the first one, the safranin is salted out in the usual manner. It gives on tanned cotton, bright bluish-red shades, very similar to those produced by rhodamine S.

—T. A. L.

Naphthfluoresceine, The Manufacture or Production of. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 3497, Feb. 18, 1895.

NAPHTHARESOREINOL (*m*-dihydroxynaphthalene), which is obtained from 2,4,1'-amidonaphthol sulphonic acid or from 2,4,1'-dihydroxynaphthalene sulphonic acid by heating with dilute mineral acids at high temperatures, can be converted into naphthfluoresceine by heating with phthalic anhydride in presence of a condensing agent such as concentrated sulphuric acid, zinc chloride, phosphoric anhydride, or oxalic acid. One method is illustrated in the following example:—45 kilos. of naphtharesoreinol, 25 kilos. of phthalic anhydride, and 20 kilos. of zinc chloride are heated for 10 hours to 200° C. After cooling, the melt is powdered and extracted with boiling water containing a small quantity of hydrochloric acid, the residue being dissolved in dilute soda-lye, from which the crude naphthfluoresceine is precipitated by sulphuric acid. The product is then filter-pressed and digested with ether, which extracts a black residu, leaving naphthfluoresceine in small brown crystals, which can be purified by recrystallisation from alcohol. The new colouring matter separates in small red needles with a greenish metallic lustre, is insoluble in benzene, sparingly soluble in ether, but easily soluble in alcohol. The solution in alcohol shows an intense green fluorescence on the addition of a small quantity of acid. The product dissolves in alkalis to a magenta-red solution with a yellow fluorescence; it gives rose shades on silk having a yellow fluorescence; and it is further observed that it can be used for the production of other dyestuffs.—T. A. L.

Blue Safranine-azo Dyestuffs, Manufacture of. S. Pitt, Sutton. From L. Cassella and Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 3488, Feb. 18, 1895.

DIAZO-SAFRANINE, when combined with β -naphthol under ordinary conditions (in presence of an excess of alkali), forms a dyestuff which, on account of its insolubility, is of little technical value. If, however, the reaction be carried out in presence of a free organic acid, especially acetic or carbonic acid, the resulting dyestuff is freely soluble in water. About 35 kilos. of safranine 8 dissolved in 1,000 litres of water are diazotised with 25 kilos. of hydrochloric acid and 7 kilos. of sodium nitrite, yielding an easily soluble blue diazo compound, which is added to the following solution:—1,000 litres of water, containing 4 kilos. of sodium hydrate and 14·4 kilos. of β -naphthol, is made faintly acid with hydrochloric acid, so as to precipitate the naphthol in a finely-divided state, 20 kilos. of sodium acetate being then added. After adding the diazo compound and allowing the mixture to stand several hours, the formation of the dyestuff is complete, and the product is precipitated with brine, when it is filter-pressed and dried. Sodium bicarbonate may be employed in place of sodium acetate, care being taken that the mixture is maintained at a low temperature, in order to keep the solution saturated with carbonic acid.—T. A. L.

New Dihydroxynaphthalene, The Manufacture or Production of a, and of certain Sulphonic Acids derived from this Dihydroxynaphthalene or from the corresponding Amidohydroxynaphthalene. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 3580, Feb. 19, 1895.

By fusing sodium 2,4,1'-amidonaphthalene disulphonate with twice its weight of potash and 0·4 part of water for six hours at 215° C. in an autoclave, it is converted into a new 2,4,1'-amidonaphthol sulphonic acid, and can be separated by acidulating the melt with dilute hydrochloric acid. This acid is sparingly soluble in cold water, whilst its salts dissolve easily, giving green fluorescent solutions. It remains unchanged on adding ferric chloride or bleaching powder. With nitrous acid it is converted into a soluble yellow diazo compound, which is unchanged when added to sodium carbonate solution. The acid will also combine with diazo compounds, yielding azo dyestuffs. When heated with five times its weight of water for four hours to 200°—210° C. in an autoclave, the amido group is replaced by the hydroxyl group, the resulting solution containing the ammonium salt of 1,4,1'-dihydroxynaphthalene sulphonic acid (naphtharesoreinol sulphonic acid). This acid is very soluble and can only be crystallised from very concentrated acid solutions. Solutions of its neutral salts are yellow with a greenish fluorescence, and the combination with diazobenzene chloride gives a yellow azo dyestuff. An isomeric dihydroxynaphthalene sulphonic acid can be obtained by heating 2,4,2'-amidonaphthol sodium sulphinate with five times its weight of 5—10 per cent. dilute sulphuric acid for four hours at 210° C. The resulting dihydroxynaphthalene sulphonic acid is readily soluble in water, but can be salted out of a concentrated acid solution by the addition of salt. Its neutral salts give greenish fluorescent yellow solutions. Ferric chloride added to a solution of the acid produces a green coloration, which rapidly turns yellow, whilst bleaching powder gives a yellowish-brown coloration. The acid can be employed for the production of azo colouring matters, and when combined with tetrazodiphenyl chloride in an alkaline solution, it gives magenta-red shades, whilst in an acid solution blue shades are obtained. When 2,4,1'-amidonaphthol sulphonic acid is heated with five times its weight of 5 per cent. sulphuric acid for four hours to 215° C., the sulphonic acid group is split off, and there results a new *m*-dihydroxynaphthalene (naphtharesoreinol) which differs from all its isomeric compounds. It is very soluble in all solvents, and crystallises from water in groups of hexagonal plates melting at about 124° C. In place of the amidonaphthol sulphonic acid employed, the corresponding amount of the 2,4,1'- or 1,3,1'-dihydroxynaphthalene sulphonic acid may be used.—T. A. L.

Direct-dyeing Colouring Matters [Blue-Blacks], Manufacture of. C. D. Abel, London. From "The Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 4018, Feb. 25, 1895.

By reacting with two molecular proportions of *p*-nitrodiazobenzene on one molecular proportion of 1,1',3,3'-amidonaphthol disulphonic acid and reducing the product obtained with sodium sulphide, there results the compound,

which can be converted into a tetrazo derivative and combined with various amines and phenols. The same compound can also be produced by employing acetyl-*p*-phenylene diamine in place of *p*-nitraniline, the resulting product being subsequently hydrolysed instead of reduced. The amido compound obtained by either method forms a black metallic powder, soluble in water with an indigo-blue colour, and in sulphuric acid with a bluish-black colour, which, on diluting with water, changes to pure blue, excess of water giving a precipitate of the free colour acid. The formation of a dyestuff is illustrated in the following example:—14 kilos. of the amido compound are converted into the tetrazo

compound by treatment with 3.5 kilos. of sodium nitrite and 20 kilos. of hydrochloric acid (20° B.). The tetrazo compound formed dissolves tolerably readily in water with a bluish-black colour, and this solution is poured into a cold solution of 6.1 kilos. of tolylene diamine kept alkaline with sodium carbonate. After a short time the dyestuff is salted out, filter-pressed, and dried. It forms a blackish metallic powder, tolerably soluble in cold and easily in hot water to a blackish-violet solution, which becomes more blue-black on adding caustic soda. The solution in concentrated sulphuric acid is greenish blue-black, which, on adding water, first turns violet-blue, and on further dilution the free colour acid is precipitated in dark flakes. The dyestuff gives deep black shades on unmordanted cotton from an alkaline or soap bath, fast to light, air, and soap. Other dyestuff components may be substituted for the tolylene diamine mentioned above— β -naphthol, for instance, giving a colouring matter which dyes bluish-black shades on cotton. Similarly, mixed tetrazo dyestuffs may be obtained by using dissimilar components, as, for example, the tetrazo compound may be combined with 1.4-naphthol sulphonic acid, and subsequently with tolylene diamine (one molecular proportion of each), when a blue-black colouring matter is produced.—T. A. L.

New Amido Base [Amidotolucylamidothiophenol], The Manufacture and Production of, and of Colouring Matters therefrom [Cotton Bluish-Reds]. A. G. Green and R. Jansen, Manchester. Eng. Pat. 4418, March 1, 1895.

THE base described is a higher homologue of that already referred to in Eng. Pat. 21,786 of 1891 (this Journal, 1895, 962), and is obtained by heating together equimolecular proportions of aniline and *m*-xylydine together with four atoms of sulphur. The base has probably the following constitution:—

($\text{C}_6\text{H}_3\text{CH}_3\text{CH}_3\text{NH}_2 = 1:3:4$), and the method employed for its production is as follows:—A mixture of 95 kilos. of aniline, 121 kilos. of *m*-xylydine, and 128 kilos. of sulphur is heated for 10–12 hours until about 102 kilos. of hydric sulphide have been evolved and the temperature of the melt has slowly risen from 200°–240° C. The melt so obtained may be employed directly for the production of colouring matters, but in order to purify it, it is distilled, crystallised from benzene, and recrystallised from amyl alcohol, from which it separates in short prisms melting at 196° C. Its acetyl derivative melts at 210°–211° C. On treatment with fuming sulphuric acid, it is converted into a sulphonic acid, of which the ammonium salt is easily soluble. Both the base and its sulphonic acid yield colouring matters on combining their diazo compounds with amines and phenols and their derivatives, and of especial value are the dyestuff components alluded to in Eng. Pat. 21,788 of 1891 (this Journal, 1895, 962), which are naphthalene derivatives containing a sulphonic acid and a hydroxyl group in the meta position. In the case of certain derivatives, containing a diazotisable group, as, for example, in those colours derived from the 1.3'.3'-amido-naphthol sulphonic acid and the 1.3'.3.4'-amidonaphthol disulphonic acid, the dyed fabric may be diazotised and combined with amines and phenols, forming very fast shades. The following example describes the production of one of the colouring matters:—The diazo compound from 24 kilos. of the new amido base is allowed to run slowly into a solution containing 35 kilos. of the sodium salt of α -naphthol- ϵ -disulphonic acid, kept alkaline by sodium carbonate. After heating to 70° C., the dyestuff is salted out and dried. It has the following formula:—

and dyes cotton from an alkaline or neutral bath, giving bluish-red shades which are bluer than the corresponding colour from dehydrothio-*p*-toluidine.—T. A. L.

Removing Gummy and other Matters from Vegetable Fibres, Improved Method of and Apparatus for. C. Wetherwax, Best, New York, U.S.A. Eng. Pat. 22,817, Nov. 28, 1895.

WITHIN a digesting vessel is a cage supporting a series of baskets, each provided with a spirally arranged partition. In the compartments so formed, the fibre is placed in a winding position and subjected to the "action of a heated liquor," which circulates in a downward direction through the fibres in the series of baskets. The gummy and resinous matters, contained in the solution finally drawn off, form a valuable commercial product.—R. B. B.

Vegetable Fibres, Direct Fixation of Certain Metallic Oxides on. A. Bonnet. Comptes rend. 1895, 121, 700–701.

EXTENDING his earlier work upon the dissociation of certain lead compounds in presence of vegetable fibres (this Journal, 1894, 34), the author finds that the hydroxides of copper, zinc, cobalt, and iron (ferrie), like that of lead, can be fixed directly by vegetable fibres. Cotton immersed in an ammoniacal solution of cupric oxide retains after washing only traces of the oxide; but by repeating the operation in the same solution after the addition of a little sodium (or potassium) hydroxide, the fibre is found to have fixed the oxide so well that even prolonged washing in running water removes none. Ammoniacal oxide of zinc (or of cobalt) alone leaves an abundant deposit in the fibre, but the amount is increased by an addition of the hydroxide of an alkali metal. Sodium ferrate also deposits ferric oxide, but oxidises the material energetically. A cupro-chromic solution, made by dissolving copper chromate in ammonia, mixed with soda or potash, fixes oxides of copper and chromium on the fibre.—W. G. M.

β -Naphthol Preparations on Cotton Fabrics, Preservation of. C. Kurz. Monit. Scient. 1895, 9, 638

THE difficulty of preserving cotton fabrics, prepared with sodium β -naphtholate, so as to keep white for a suitable length of time, has been overcome by the author in the following manner:—

The essential part is the employment of a double salt of fluoride of antimony and sulphate of ammonium (47 per cent. Sb_2O_3), which is added to the preparation of sodium β -naphtholate.

The following example gives the quantities generally employed:—40 grms. of β -naphthol are dissolved in 1 litre of water and added to 80 c.c. of caustic soda of 38° B.;

10 grms. of the crystallised antimony salt, dissolved in 50 c.c. of boiling water, are then added gradually, stirring meanwhile, until the flocculent precipitate of oxide of antimony formed, is completely redissolved.

Cotton fabrics prepared in this preparation will keep white for more than eight days. This process is also good for the preparation of cotton yarns. The preparation is employed chiefly for such substances as α - and β -naphthylamine, benzidine, toluidine, &c. Also, for similar proportions of paranitraniline, β -naphthol, and β -naphthol R., for metanitraniline, dianiline, &c., with or without the addition of sulphocyanates to the preparation.

For printing with the basic colouring matters on tannin under azoic colours, the presence of the antimony salt facilitates the fixation of these colours, by forming tannate of antimony on the fibre. Nevertheless, this process is imperfect, inasmuch as the presence of caustic soda in excess is detrimental to the formation and to the complete fixation of the tannate of antimony, and results nearly alike were obtained in this way, whether the cloth prepared with tannin was passed through a solution of sodium naphtholate containing a salt of antimony or not.

The author states that this process has been in actual use now for more than a year.—T. W.

β -Naphthol Preparations on Cotton Fabrics, Preservation of. Reply to C. Kurz by L. Caberti. Monit. Scient. 1895, 9, 772.

C. Kurz states that the excess of caustic soda is detrimental to the formation and fixation of basic colours. But the author points out that in his process, a certain quantity of glycerin is added, whereby the quantity of caustic soda employed to redissolve the oxide of antimony precipitated, is reduced to a minimum, and in consequence the fixation of the basic colours is not impeded by any excess of alkali, as it would be according to Kurz's process. Glycerin in presence of alkalis, it is pointed out, is a very good solvent for certain metallic oxides, such as the oxides of iron, chromium, tin, &c. In certain cases it is even indispensable for the purpose of dissolving any appreciable quantity of metallic oxide—in the present case, oxide of antimony.

The author denies that in his process the same results are obtained, whether the pieces prepared with tannin are treated with sodium naphtholate solution, either containing a salt of antimony or not.—T. W.

Tannic and Gallic Acids, Absorption of, by Silk. L. Vignon. Comptes rend. 121, 1895, 916–919.

EXPERIMENTS have been made under varying conditions of time, temperature, and dilution as to the behaviour of silk skeins when immersed in tannin and gallic acid solutions, and the following conclusions arrived at:—1. Ungummed silk can absorb gallic and tannic acid. 2. The absorption of gallic acid at a temperature of 80° C., which, with a 1 per cent. bath, is practically nil, can amount to 7–8 per cent. of the weight of the silk when the bath contains 4 per cent. 3. Tannin is absorbed much more readily than gallic acid, the limit being about 25 per cent. of the weight of the silk. 4. In the case of solutions containing gallic and tannic acids in equal quantities, only the latter is absorbed, and the increase in weight of the silk corresponds to the strength of the solution in tannic acid. The results can be applied as methods for estimating tannin in products employed for dyeing and weighting silk.—T. A. L.

Chrome Leather, the Alizarin Colours applied to. H. Burgess. Leather Trades Circular and Rev. 1896, 396–397.

THE success which has attended the application of the alizarin dyestuffs to wool mordanted with chromium compounds is well known. When it was attempted to use these dyestuffs for bark and sumach tanned leather, it was found that the high temperature (about 60° C.), which was necessary, even in an alkaline bath, caused irretrievable damage to the leather. Since chrome leather will withstand a higher temperature than will bark or sumach tanned goods, the author performed some experiments in the hope that the alizarin dyestuffs might be successfully applied to

the new leather. The expectation that the leather itself, being a chromium compound, would act as its own mordant, and be dyed directly, was not realised; for the dyeing was found to be very partial at any temperature below 100° C., and this is too hot even for chrome leather. By mordanting and dyeing in baths at moderate temperatures, however, much better success was obtained. The leather is introduced into the cold bath, and the temperature raised—in the mordant bath, to 40° C., and in the dyeing bath to 60° C.—in the course of 20 minutes, and maintained at the same point for another 20 minutes. The dyeing bath contained the dyestuff dissolved in 5 per cent. ammonia (1 c.c. for each grm. of dyestuff).

The following are among the results quoted, the quantities of mordants and dyes being percentages on the weight of the dry leather:

Alumina Mordant.—19 per cent. $Al_2(SO_4)_3 + K_2SO_4$ (sic) and 2 per cent. of $C_2H_2O_4$.

Dye: 25 per cent. Alizarin W.B.—A deep rich crimson shade.

25 per cent. Alizarin W.R.—Same as W.B., but not quite so blue.

25 per cent. Alizarin Orange.—A bright red shade, much brighter than either Alizarin W.B. or W.R.

30 per cent. Anthracene Brown.—A dark brown, almost black.

25 per cent. Anthracene Brown.—Dark brown.

15 per cent. Anthracene Brown.—Chocolate.

5 per cent. Anthracene Brown.—A very pretty iron grey shade.

15 per cent. Alizarin Orange, and 10 per cent. Anthracene Brown.—A deep rich claret.

3 per cent. Cærulein.—A deep green (yellow shade).

5 per cent. Alizarin Blue.—A full bright blue.

5 per cent. Cærulein.—Same as with 3 per cent., but much deeper shade.

Tin Mordant.—5 per cent. $SnCl_2$ and 2 per cent. $C_2H_2O_4$.

Dye: 25 per cent. Alizarin W.B.—Redder than with alumina mordant.

25 per cent. Alizarin W.R.—Redder than with alumina mordant.

25 per cent. Alizarin Orange.—Yellower than with alumina mordant.

With anthracene brown—quantities as with alumina mordant in each case—good shades were obtained, slightly redder brown than with alumina mordant.

Iron Mordant.—8 per cent. $FeSO_4$ and 2 per cent. $C_2H_2O_4$.

Dye: 25 per cent. Alizarin W.B.—Dark maroon.

25 per cent. Alizarin W.R.—Dark maroon.

25 per cent. Alizarin Orange.—Dark crimson.

20 per cent. Anthracene Brown.—Dark brown, as dark as the shade obtained with 30 per cent. on alumina mordant.

2 per cent. Anthracene Brown.—A very pretty stone drab.

2 per cent. Alizarin Blue.—Full blue shade, not so good as with alumina mordant.

3 per cent. Cærulein.—Dark olive green, very good shade.

The best chromium mordant proved to be 3 per cent. $K_2Cr_2O_7$ and 2 per cent. $Na_2S_2O_3$ with 1 per cent. H_2SO_4 .

Combinations of colours may be successfully used in order to still further vary the shades, and for the same purpose almost any of the acid dyestuffs may be applied.

The alizarin blue and cærulein dyes are quite fast. The action of light is under investigation.—A. G. B.

PATENTS.

The Utilisation of a Waste or Nearly Waste Product, [Locust Beans], Improvements in or Appertaining to, and the Manufacture of a Useful Gum or Gummy Compound therefrom. P. C. D. Castle, Liverpool. Eng. Pat. 24,877, Dec. 21, 1894.

THIS is a development of Eng. Pat. 8793, 1893 (this Journal, 1894, 410), describing the treatment of the beans of the locust or carob tree for the preparation of a gum

to replace tragacanth. The beans are extracted twice with 15 to 20 times their weight of water for 3 or 4 hours at a temperature not exceeding 82° C. The liquid is separated in a centrifugal machine, mixed with 1 part per mille of phenol, filtered through silk—as used in flour dressing—5 per cent. of farina added, and the whole well agitated for half an hour. The apparatus is lined with lead, aluminium, or silver. The gum is used for sizing, colour printing and dyeing; and if prepared without antiseptic, may be employed for confectionery.—E. H. L.

Printing of Cotton or Linen Warps or Warp Yarns. Improvements in, in connection with Sizing or other Treatment thereof for Weaving Purposes. T. Pickles, Burnley. Eng. Pat. 2676, Feb. 7, 1895.

AFTER bleaching, dyeing, or otherwise preparing upon the warp beam, the warps pass to a drying cylinder, where all moisture is driven off, and then through suitable printing apparatus and steam box. The bad effects of the pressure required in printing, when the warp yarns are in rope form, are thus avoided. From the steam box the warps pass to the sizing machine with or without the interposition of a second drying cylinder.—R. B. B.

Dyeing of Cotton or Linen Warps or Warp Yarns. Improvements in, in connection with Sizing or like Treatment thereof for Weaving Purposes. T. Pickles, Burnley. Eng. Pat. 2764, Feb. 8, 1895.

SEE Eng. Pat. 2676 (foregoing). The warps are prepared on the beam, pass around a drying cylinder and thence either to the sough box containing a mixture of dye and size, or to a separate dye box. In the latter case the warps may be caused to pass several times through the dye box until the desired colour is obtained, and afterwards sized and dried in the ordinary manner.—R. B. B.

Dyeing or Colouring Asbestos Cloth or Fabrics. Improvements in. L. Cresswell, Calderley, Yorks. Eng. Pat. 3123, Feb. 13, 1895.

THE object of this invention is to dye on asbestos fire-screens or fireplace blinds, colours which are not affected by exposure to very high temperatures. For this purpose, after dyeing by some known process, the cloth is passed through a bath containing ammonio-nitrate, acetate, or tartrate of silver together with dextrin in solution. It is then dried by the action of heat, e.g., by ironing, with a sheet of parchment between the cloth and the heated iron. Indelible dark colours are thus produced.—R. B. B.

Chemically Cleansing Wool and Woollen Fabrics and Rugs. A Process for. E. Lasbordes, Castres, France. Eng. Pat. 3590, Feb. 19, 1895.

THIS is a modification of the carbonising process for removing vegetable substances from wool. Panama, hawthorn, or similar wood broken into fragments is soaked in water for 2 hours. In this bath the wool is steeped for at least 4 hours, after which it is drained and dried. To prepare the acid bath, calcium sulphate is added to H_2SO_4 at 13°–15° B. to remove nitrous compounds, and after standing some time the liquid is decanted and diluted to 2·5°–5° B. Sulphurous acid and sodium bisulphite are added, with the result that during carbonisation sulphuric acid is formed, and in its nascent state is more than usually active. After steeping in acid, carbonisation takes place at a temperature not exceeding 50° C. Another bath of Panama, and one of dilute sodium carbonate, complete the process. For goods which are to be dyed, the acid bath may consist of hydrochloric and tannic, instead of sulphuric and sulphurous acids.—R. B. B.

Saving Dyestuff in Dyeing with Indigo Blue, A Process for. E. Cabiati, Milan, Italy. Eng. Pat. 14,704, Aug. 2, 1895.

FOR goods to be dyed a plain blue, a net-shaped groundwork is printed in aniline black on one or both sides of the material, which is then dyed in the indigo vat. For prints in the reserve style the resist is first printed, and then the aniline black, before dyeing. When printing with mordants, the black is applied after the mordant.—R. B. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Tartaric Acid and Alkaline Tartrates, Some Reactions of. L. M. de la Source. Comptes rend. 121, 774–776.

THE addition of a small quantity of tartaric acid to a dilute solution of potassium acetate, produces immediately a precipitate of acid potassium tartrate, but with a concentrated solution of the acetate no such precipitation occurs. A neutral alkaline tartrate is decomposed by acetic acid when subjected to spontaneous evaporation in the cold, and under similar conditions an alkaline acetate is decomposed by potassium acid tartrate. Calcium sulphate in excess decomposes neutral alkaline tartrates forming calcium tartrate and an alkaline sulphate. Potassium sulphate and chloride evaporated with tartaric acid lose part of their respective acids.—J. G. W.

Calcium Chromite, Neutral, Crystallised, Production of. E. Dufau. Comptes rend. 1895, 121, 689–691.

A MIXTURE of 115 grms. of chromium trioxide and 45 grms. of quicklime, acted upon by a current of 700 amperes and 50 volts in the electric furnace, gave a green crystalline mass containing two kinds of crystals, yellowish, similar to those prepared by Moissan ($4\text{CaO} \cdot \text{Cr}_2\text{O}_3$), and dark needles, several millimetres in length, occurring in groups; the cover of the furnace was also covered with these crystals. The crystallised portion treated with strong hydrochloric acid gave out much heat, with a copious evolution of chlorine, and the production of a green colour in the liquid. Finally the crystals were treated with boiling hydrochloric acid until they were no longer attacked. The residue consisted of prismatic needles with metallic reflection, giving a clear green powder; the smaller crystals being transparent. Their hardness was about 6, and their density 4·8 at 18° C. The formula was $\text{CaO} \cdot \text{Cr}_2\text{O}_3$, and thus agreed with that of the olive-green powder obtained by Gerber in 1877. Chlorine at a red heat decomposed the chromite with superficial formation of calcium chloride (oxygen being evolved), the chromium oxide being unattacked. HCl and HF give calcium fluoride and chloride at a red heat, leaving the chromium trioxide crystallised. The hydrochloric acid gas acting with incandescence and at a low red heat. HNO_3 and SO_2H_2 are without action. —W. G. M.

Boric Acid, The Methyl-Alcohol Process of Separation simplified. H. J. and Dupasquier. Monit. Scient. 1895, 709.

See under XXIII., page 136.

PATENTS.

Chlorates of Sodium and Potassium, Improvements in the Manufacture of. J. Hargreaves, Farnworth-in-Widnes, and T. Bird, Cressington. Eng. Pat. 18,526, Oct. 1, 1894.

SODIUM chlorate is produced by passing chlorine through a series of absorbing vessels, charged with caustic soda or with sodium carbonate or bicarbonate solution. The excess of chlorine is utilised by passing it through a coke-packed tower, into which a weak soda solution is run. The sodium chloride precipitated in the process is drawn off into a filtering vessel with a perforated bottom, a current of steam being forced downwards to dissolve out the sodium chlorate mixed with the salt. The solution is concentrated, and the salt removed as it falls, until a liquor of sp. gr. 100° to 120° Tw. is obtained, from which sodium chlorate is crystallised. Potassium chlorate is obtained from sodium chlorate by the addition of an equivalent of potassium chloride in solution, followed by crystallisation.

The absorbing vessel is divided, by a perforated partition, into an inner and outer compartment, the chlorine passing into the former—whence, by the action of an agitator, the soda solution is forced to a higher level in the outer compartment, and continually returns as foam to be acted upon by the chlorine. When sodium carbonate solution is used, bicarbonate is formed in part, and precipitates; but this, with undissolved carbonate, is kept in constant suspension and in contact with the gas. The absorbing vessels, arranged in series, are interchangeable.—E. S.

Ammonia from Sewage Effluent and other Weak Ammoniacal Liquors, Improvements in the Recovery of. T. Twynam, Egham, and F. E. Matthews, Englefield Green, Surrey. Eng. Pat. 2625, Feb. 6, 1895.

SEWAGE effluent, or other weak ammoniacal solutions, are filtered through a mixture of ferric hydroxide and phosphate, or of hydrated phosphoric iron ore, which may be mixed with an inert substance, or the latter may be superposed. The filtering material may be placed within a hollow metallic jacket for convenience of expelling the ammonia after the filtration by means of steam or hot air, the ammonia being suitably condensed. Or the ammonia-charged material may be used directly as a fertiliser. The filters are arranged in series.—E. S.

An Improved Detergent or Washing Powder. J. T. A. Walker, Rishton, near Blackburn, Lancashire. Eng. Pat. 3466, Feb. 18, 1895.

IN order to obtain a harmless yet active preparation of ammonia for laundry purposes the inventor mixes a salt of ammonium, preferably the sulphate, with commercial sodium carbonate, in the proportion of one molecule of the former to two of the latter. To avoid loss of ammonia the salts are mixed in an anhydrous state, or are coated with a substance such as paraffin wax. The preparation may be used alone or with a super-fatted soap base. In the latter case 10 per cent. of the detergent powder is added to the soap base. Where artificial perfume is desired, a trace of nitrobenzene may be added. By the use of sodium bicarbonate, acid ammonium carbonate is produced and all risk of injury to the hands obviated.—C. A. M.

Caustic Lyes of the Alkalis, Process for the Production of. O. Imray, London. From The Chemische Fabrik Rhenania, Aachen, Germany. Eng. Pat. 3185, Feb. 18, 1895.

CAUSTIC alkalis are produced by first treating alkaline carbonate liquors with a mixture of calcium carbonate and caustic lime, and then treating the separated imperfectly causticised lye with fresh lime to render it completely caustic. In practice, crude lye diluted to about 17° B. with weak liquors (washings, &c.) is placed in a vessel having iron gratings at the top, provided with a central opening for the introduction of a sieve-like vessel containing lime, suitably suspended. Steam is then blown in from the bottom until the temperature rises to 70° C., when the lime is admitted. After settling, the lye is drawn off and fresh lye is added, to be boiled together with the remaining sludge of calcium carbonate and hydrate. This second operation converts the sludge wholly into carbonate, which is removed after the partially causticised lye is withdrawn. The lye is then treated as in the first operation, with fresh lime, and the liquid obtained is converted into solid caustic soda. The resulting sludge of calcium carbonate and hydrate is again used as described.—E. S.

Chlorine, Manufacture or Production of, Improvements in. J. Y. Johnson, London. From Verein Chemischer Fabriken of Mannheim, Germany. Eng. Pat. 4267, Feb. 27, 1895.

THIS invention is an addition to and development of Eng. Pat. 10,601, 1891 (this Journal, 1895, 483), for producing chlorine by reacting in a series of (A) chambers upon hydrochloric acid by nitric acid, communicating with a second series (B) traversed by strong sulphuric acid for decomposing the NOCl formed in the A chambers, and with a third series (C) constituting the regenerating apparatus, besides supplementary vessels, shown in the drawing given with the abstract of the earlier patent. These vessels, which before were in each series superposed, are now shown arranged side by side. When the reaction chambers (A) are used, the acid mixture assigned to them is successively proportioned as 69:23:8, for adjustment to the quantity of HCl gas reaching each; but the chambers are shown equal in size, so that the acid mixture after use may be saturated in each chamber with HCl. The acid running off from the A chambers is conducted to a closed vessel to be heated to 130° C. to free it from nitrogen compounds. The nitrous

sulphuric acid discharged from the B series of chambers, and containing a certain proportion of chlorine, is taken to another closed vessel, which may be of cast iron, to be heated to 130° C., when most of the chlorine in solution will escape as HCl and NOCl, and the gases are led into one of the B chambers. Also, the nitric acid regenerating column is divided at about two-fifths of its height, at which point as much nitric acid containing chlorine is drawn off as corresponds to the quantity of chlorine remaining behind in the nitrous sulphuric acid previously heated.—E. S.

Cyanides, Process for Manufacturing out of Molasses and Lyes resulting from Beetroot Molasses. H. Reichardt and J. Bueb, Dessau, Germany. Eng. Pat. 7171, April 8, 1895.

THIS process consists in directly leading the gases resulting from the dry distillation of lyes and molasses through a system of fire-brick channels raised to a bright red or white heat. The nitrogen contained in the gas is converted into ammonium cyanide mixed with a small amount of ammonium carbonate. The gas is then passed through a solution of iron salts, the ferrocyanide so obtained serving as an initial material for the production of yellow prussiate, or cyanide of potassium. The carbonic acid and hydrocarbons which are present in large quantities in the products of distillation, are entirely freed from nitrogenous compounds, and can be utilised in any suitable manner.

—J. L. B.

Obtaining Cyanides from Gases [Coal Gas], Improvements in Apparatus for. W. Foulis, Glasgow, and P. F. Holmes, Huddersfield. Eng. Pat. 15,168, Aug. 12, 1895.

APPARATUS is shown for use in the process for obtaining cyanides from gases, forming the subject of Eng. Pat. 9474, 1892 (this Journal, 1893, 511). Scrap iron is treated with hydrochloric acid in tanks, and the iron liquor is pumped to an elevated storage tank, whence it is taken to precipitation tanks, for treatment with an alkaline carbonate. After settling, and withdrawal of the supernatant liquor, alkali and water are added, and steam is blown in, and the liquid, with the iron carbonate in suspension, is taken through pipes by a steam lifter to a mixing chamber fitted with agitators, immediately over a pair of scrubbers of the horizontal rotary type. Gas, freed from ammonia, but retaining cyanides, is passed through the scrubbers, after admission of the mixture. The outflowing liquor contains an alkaline ferrocyanide in solution, and is passed into a settling tank, whence the liquor is taken to a pair of pans, one over the flue and the other over the fire, the thin liquor being passed into the latter and the thicker liquor into the former. The cake obtained is treated as described in the former patent.—E. S.

Evaporators for obtaining Common Salt, and for Analogous Purposes, Improvements in or relating to. T. Scott, Edinburgh. Eng. Pat. 15,197, Aug. 13, 1895.

See under 1., page 102.

IX.—BUILDING MATERIALS. CLAYS, MORTARS, AND CEMENTS.

Cement for Metals, Experiments with. M. Rudeloff. Mitt. aus d. Königl. techn. Versuchsanstalt zu Berlin. 13, (6), 290—302.

THIS material is a hard, brittle substance, containing much sulphur, and is intended for use in a fused state to fix iron stay braces in stone, brickwork, or cast iron, as well as for filling up and repairing fissures in foundations, &c., faults in iron castings, setting machinery and stuffing collar joints in gas or water pipes. These purposes it is claimed to be adapted for by its property of fusing at a low heat to a watery consistency, whereby it is enabled to penetrate into cracks and holes, where it expands on cooling and adheres firmly to stone, brick, metal, or wood, and is said to resist the action of acids, moisture, and oils.

A particular make when tested gave the subjoined results:—

Fusion occurred at $119^{\circ}\text{C}.$; when heated further the substance became thicker, but fluidity was regained on cooling, accompanied by stirring. To avoid ignition, the fusing should be effected otherwise than over a naked flame. The cooled material quickly sets, and its volume decreases some 0.37 per cent. at the same time. When poured into cold iron moulds, it sets with a concave surface. It does not adhere to cold metallic surfaces, but if they have been warmed, sets fast, and can only be chipped off with a hammer. Used for setting stay braces in iron, the resulting power of resistance is about equal to that of sulphur—provided the hole be about 125 mm. deep and rather wide compared with the diameter of the rod—and superior to both lead (by some 15–20 per cent.), and Portland cement (by 65–75 per cent.).

The cement in question was able to withstand a pressure of 4.95 kilos. per sq. mm. when in the form of cubes, and of 10.3 kilos. per sq. mm. when in the condition of flat blocks $10 \times 80 \times 80$ mm. It is found to make a thoroughly sound packing for collar joints in iron piping, but can withstand neither dilute sulphuric acid nor mineral oils. Atmospheric conditions, however, have but little influence.

—C. S.

PATENTS.

Fire-Clay, Refractory and Non-Conducting Bricks and Blocks, Building Bricks, or the Like, Improvements in or relating to the Manufacture of. F. Young, Walton, Lancashire. Eng. Pat. 3608, Feb. 19, 1895.

THE new article of manufacture has as ingredients, silica with only sufficient alumina or alkali to cause it to firmly adhere. Two good recipes for its composition are as follows:—

1. Sand or other silica, 50 to 80 per cent.; waste from alkaline silicate manufacture, 5 to 15 per cent.; a good aluminous fire-clay, 5 to 15 per cent.

2. Silica, 60 to 85 per cent.; the waste product of silicate of soda manufacture, 5 to 15 per cent.; aluminate of soda, 2 to 5 per cent.

An extremely refractory brick is thus obtained, and waste material is utilised.—V. C.

Fireproof and Insulating Compounds, Manufacture of. A. Inschenetzky, St. Petersburg. Eng. Pat. 5254, March 12, 1895.

THE basis of these materials is asbestos, which is cemented together by means of silica introduced in a soluble form from which it separates either in the form of the colloid hydrate, or by chemical combination with other bodies introduced into the mass. If the material is required to be waterproof it is saturated with rosin or other suitable material, and subsequently heated sufficiently to drive off any volatile matter.

When used for insulating purposes the material is termed "Megohmite," when used for other purposes it is called "Uralite."—V. C.

X.—METALLURGY.

Silicon, Action of, on Iron, Chromium and Silver. H. Moissan. Comptes rend. 121, 621–626.

EXPERIMENTS upon the action of silicon on the three above-named metals show that the action may take the three following courses:—

1. The solid silicon, owing to its vapour tension, unites with the solid metal at a temperature of $1200^{\circ}\text{C}.$ and yields, by an action analogous to cementation, a true silicide, the melting point of which is lower than that of the metal.

2. The liquid silicon unites with the liquid metal.

3. The silicon dissolves in the liquid metal but does not form a combination with it, or produces a very unstable one, and separates out in the crystalline form at the moment of solidification of the metal.

The two first reactions apply to iron and chromium, which form silicides of the composition SiM_2 , whilst the

latter applies to silver which does not form a compound with silicon.

Iron silicide occurs in small prismatic crystals, with a density of 7. It is attracted by a magnetic needle. Hydrofluoric acid in aqueous solution attacks it readily, but it is only acted upon slowly by hydrochloric acid, even when powdered finely. Nitric acid has no appreciable action; but aqua regia attacks it with the formation of silica.

Chromium silicide resembles iron silicide very closely in its properties. It is harder than quartz and even than corundum.—J. G. W.

High Silicon Iron in the Blast Furnace, Working of. J. S. Kennedy. Eng. and Mining J. 1895, 61, 42.

MANGANESE, apart from its value in protecting silicon from oxidation in the cupola mixture, acts as an aid in the manufacture of high silicon or "soft" irons. A hot furnace and basic slags are essential to the combination of manganese with iron. The presence of manganese both in the iron and in the basic slag, tends to an increase of their fluidity, and allows of high furnace heats without injurious consequences. The author found no difficulty in running smoothly on an American-Scotch "soft" iron containing 4–5.5 per cent. of silicon, the slag containing 30–31 per cent. of silica, but there was sufficient manganese in the ore mixture to ensure a content of from 2–2.3 per cent. in the pig-iron.

The highest silicon iron ever made by the author contained 8.75 per cent. of silicon; it contained only a trace of manganese and the slag was normally an acid one.

The following is an analysis, made some years ago, of a Scotch ferro-silicon. The iron was silvery white in colour and had an irregular fracture:—Iron, 83.16; manganese, 3.86; silicon, 10.55; phosphorus, 0.04; sulphur, 0.03; carbon (graphite), 0.52; carbon (combined), 1.84. The percentage of total carbon (2.36) is very small in an iron containing so much silicon.

In the Ashland furnace, an iron has been made containing 12–13 per cent. of silicon.—A. S.

Iron, Boride of, Its Preparation and Properties.

H. Moissan. Bull. Soc. Chim. 1895, 956–959.

BORIDE of iron may be prepared by leading a slow current of chloride of boron vapour over pure reduced iron, contained in a porcelain tube at a dull red heat, when ferrous chloride is formed and distilled over, whilst the required boride is left; or by heating pure iron in a porcelain boat, brasqued with a sufficient quantity of boron, in a gentle stream of hydrogen, at 1100 or $1200^{\circ}\text{C}.$ After cooling in hydrogen, the residue is boride of iron which, if it contain about 9 per cent. of boron, will be very crystalline, and may be easily fractured along very marked planes of cleavage; and may be traversed by long needles which are often iridescent. The boride, thus formed by cementation, and containing 8 to 9 per cent. of boron, fuses at $1050^{\circ}\text{C}.$ But when the boron exceeds 10 per cent., fusion is far less easy, the fracture is conchoidal, and the crystallisation confused; whilst a 20 per cent. sample can be fused only with difficulty in a gas-carbon fire. In the electric furnace, a current of 300 ampères and 65 volts may be made to produce a large quantity of the compound within the space of 5 or 6 minutes, if fragments of iron be placed in a boron-brasqued crucible; but the temperature must not be excessive or crystalline boride of carbon will also be formed from the carbon of the crucible. On treating fragments of the crude boride, as it is formed by the above processes, with hydrochloric acid diluted with two or three volumes of water, the excess of iron is removed, and a crystalline residue is left, which should be washed successively with water, alcohol, and ether, and then dried; it has a composition corresponding to the formula BoFe . This boride is yellowish-grey in colour, and has a specific gravity of 7.15 at $18^{\circ}\text{C}.$ In dry air or in oxygen the crystals are unaltered, but in moist air they become covered with an ochreous layer.—W. G. M.

Japanese Alloys. Dingler's Polyt. J. 298, [3], 72.

THE following notes are based upon the statements of individual workers, who have revealed the composition of Japanese alloys, hitherto kept a secret.

"*Shakdo*" is copper alloyed with 1–10 per cent. of gold. The articles manufactured of this composition, after being polished, are boiled in a corrosive mixture consisting of copper sulphate, alum, and verdigris, and thus attain a beautiful bluish black colour. This colour is due to the evenly distributed gold, tests with pure copper yielding adverse results. The intensity of the shade depends essentially upon the gold content of the colouring, 1–2 per cent. of gold produces a rich bronze colour. "*Shakdo*" is employed in the manufacture of swords, scabbards, buckles, brooches, and decorative work. When boiled with the above-mentioned corrosive, the surface of the alloy is oxidised to a copper-red shade.

"*Gin-shi-bu-ichi*" (so called quarter-silver) consists of copper alloyed with 30–50 per cent. of silver. The jewellery prepared from this alloy has a rich grey colour which finds much favour in Japan.

"*Mokume*" is a compound of several different coloured alloys and simple metals which are arranged so as to produce an ornamental effect. Damascened goods are prepared as follows:—30–40 thin plates of gold, *shakdo*, silver, rosette-copper, and *gin-shi-bu-ichi* are soldered one over the other in varying order. Holes of different forms and sizes are bored in the plates, which are then hammered out and boiled in the corrosive mixture already mentioned, whereupon the different colours are developed.

"*Sin-chu*" (brass). The finest kind of Japanese brass consists of 10 parts of copper and 5 parts of zinc, a less valuable kind, of 10 parts of copper, and 2·7 parts of zinc.

"*Karakane*" (bell-metal). According to the size and used of the bells one of the four following alloys is used:—

1....	10 pts. copper,	4 pts. tin,	$\frac{1}{2}$ pt. iron,	$\frac{1}{2}$ pts. zinc.
2....	10 "	2 $\frac{1}{2}$ "	1 $\frac{1}{2}$ pts. lead,	$\frac{1}{2}$ pt. zinc.
3....	10 "	3 "	2 "	1 "
4....	10 "	2 "	2 "	$\frac{1}{2}$ pt. iron.

In preparing the alloy, the copper is melted, and the other metals added in the above order. The best bells are cast from the first alloy, large bells from the third. For all the alloys above described, suitable solders are employed, the following are their respective compositions:—

Karakane.....	20 pts. brass,	10 pts. copper,	15 pts. tin.
Sin-chu (a)....	10 "	1 $\frac{1}{2}$ "	6 " zinc.
Silver.....	3 "	1a and 10 pts. silver.	
Gin-shi-bu-ichi	5 "	1a " 10 "	1a and 3 pts. zinc.
Mokume.....	1 $\frac{1}{2}$ "	1a " 10 "	
Shakdo.....	3 pts. shakdo,	10 pts. zinc.	
Tin.....	10 pts. tin	5 " lead.	

Amongst the metal goods which arrive in Europe, are some with lustrous red surfaces which are generally considered to be lacquered or enamelled. This, however, is not the case, the appearance in question being due to a coating of red oxide of copper, produced by boiling the articles in the already mentioned corrosive liquid.—J. L. B.

The Silver Deposits of Zechan and Dundas, Tasmania. W. F. A. Thomae. J. Inst. Mining and Met. Dec. 1895.

The lodes exploited for lead and silver in this district may be classed either as fissure veins or irregular deposits, and contain the following valuable minerals:—Galena (with silver ranging from 10 to over 200 oz. per ton), argentiferous iron pyrites (sometimes yielding 146 oz. of silver per ton), cerussite, anglesite, pyromorphite, erocoisite, native silver with silver chloride, fahlerz, bournonite, jamesonite, and in one place a variety of leadhillite. Of objectionable minerals, sphalerite with from 2 to 5 oz. of Ag per ton usually accompanies galena in small proportions. Tin occurs in one or two localities, the maximum in any ore offered for sale having been 0·75 per cent.; arsenic, and antimony (in bournonite and jamesonite), rarely occur in any quantity. The concentrating mills are for the most part unsuitable, steam-jiggers at one mine losing at least 30–50 per cent. of the gross contents of the ore delivered to them. In all cases there is a greater loss of silver from the galena by machine concentration than by hand treatment, the loss, which, in the table of assays quoted, ranges from 0·21 to

0·56 oz. of silver per unit of lead, is attributed to the excessive crushing of a galena in which much of the silver is present in mere admixture as a silver ore, that may be carried off in the slimes. No fair comparison of concentrators can be effected unless the trials be made with the same ore. Only two attempts at local smelting have been made, one of which never had any prospect of success, whilst, in the other, a water-jacketed blast furnace, with a capacity of 60 tons per 24 hours, smelted over 3,000 tons of ore, and then stopped because the supply was exhausted.

—W. G. M.

The Cyanide Process, The Chemistry of.—Is the Double Zinc Potassium Cyanide a Solvent for Gold. J. S. C. Wells. Eng. and Min. J. 1895, 60, 584.

The author describes a series of experiments which he made to test the accuracy of a statement by Feldman (this Journal 1894, 952), that gold is soluble in a solution of zinc potassium cyanide. He draws the following conclusions from the results of his tests:—1. Zinc potassium cyanide is a solvent of gold, but of less power than potassium cyanide. 2. Zinc potassium cyanide is not decomposed by alkali into free potassium cyanide and potassium zincate. 3. Zinc potassium cyanide, in presence of potassium cyanide, can have no solvent action on gold, and is therefore valueless in the ordinary cyanide process. 4. The estimation by silver nitrate in presence of free potash, does not indicate the cyanide available as a solvent of gold, but the total amount of cyanogen in the solution.—A. S.

Gold and Silver Ores and other Compounds; The So-called "Selective Action" of very Dilute Solutions of Potassium Cyanide upon. J. Maclear. J. Inst. of Mining and Met., Dec. 1895.

The statement in the MacArthur-Forrest patents, as to the selective action of dilute solutions causing gold and silver to dissolve, in preference to the base metals, and the more definite interpretation thereof given in the judgment of the Court of Appeal (that "a strong solution attacks the base metals without attacking the gold, whereas a weak solution is feeble and *nil* on the base metals but attacks the gold"), led the author to institute a series of experiments on the subject. Gore's experiments showed that whilst many base metals (Al, Zn, Cu, Sn) were electro-positive as metals, others (Pb and Fe, as well as Hg) were electro-negative; and the rate of solubility varied in a similar way. But in gold ores the base metals occur in combination; yet even under these circumstances cyanide solutions of 0·5, 2, and 5 per cent. strength, acting upon freshly precipitated oxides of iron, zinc, copper, and lead, mixed with finely divided gold, dissolved, in 24 hours, more of the former than of the latter; and the proportion of gold passing into solution was small as compared with that of the oxides. With native oxides the rate of solution may be slower, but still may often be great as compared with the gold; but in the cyanide treatment of ores, the preliminary addition of alkalis often produces hydroxides, which would behave similarly to those experimented with. Carbonates are like oxides in respect of solubility. Sulphides are acted upon irregularly, in a manner and to an extent which depend upon physical and chemical conditions; but, broadly speaking, they too are far more easily attacked than gold. The base metals of oxidised ores, containing soluble sulphates, would dissolve even in water, and therefore also in cyanide solutions. But too little attention has been given to electro-chemical action. Skey pointed out that mercury, being electro-negative to gold in cyanide solutions, the use of cyanide in gold-milling caused the solution of any salts of mercury which had caused flouzing; whilst the mercuric cyanide produced dissolved gold rapidly, with deposition of mercury. Many of the natural sulphides, as well as manganese peroxide and magnetic iron ore, are electro-negative to gold in cyanide solutions, and are sufficiently good conductors to allow of galvanic couples being set up, which expedite the solution of the gold. Similarly couples may be formed by gold with the particles of iron worn from the shoes and dies of the stamps, iron being the negative element. Further, the mere passage of a current of elec-

tricity though a solution in which finely divided gold is suspended was found to hasten the rate of solubility, although the gold was not in metallic contact with either electrode.

The greater comparative proportion of gold to base metal in weaker solutions is due mainly to the fact that in all there is a large excess of cyanogen over that necessary to combine merely with the gold, and the larger the excess the more foreign substances may be expected in solution; whilst gaseous oxygen, being more soluble, and therefore present in greater quantity, in the more dilute solutions, these will attack the precious metal more readily. Thus, it is considered, the action cannot properly be described as "selective."—W. G. M.

Alloys of Copper and Zinc; their Mechanical Properties.
G. Charpy. Comptes rend. 1895, **121**, 494—496.

THE brass alloys are not influenced by the time of heating or cooling whilst undergoing thermal treatment; so that the condition of the metal depends solely upon the amount of mechanical work to which it has been submitted in the cold, and the maximum temperature of the last annealing. Hence the author has selected this series for exhaustive examination. Alloys containing from 50 to 100 per cent. of copper were cast, and then hammered or rolled until the deformation or extension at the moment of rupture, as observed during mechanical testing, was practically *nil*. Specimens thus hardened to the maximum point were annealed at various temperatures, increasing by 50° C. each time, up to the fusing point of the metal. At each stage tests were made by tension and compression, and these have led to the following conclusions:—1. The strength of cast metals, depends upon the casting temperature, being greatest as this approaches the fusing point; also upon the rate of cooling, a rapid solidification giving the best result. 2. The temperatures of annealing may be divided into four zones, varying in extent for different alloys; the first includes those at which no softening effect is observable in the annealed metal, and extends only up to 350° C. for copper, and to temperatures which are lower as the percentage of zinc increases. In the second zone, the softening effect is a function of temperature, almost absent when copper is being treated, this zone extends as the zinc is increased, until for the 40 per cent. alloy it reaches almost from the ordinary temperature nearly to the fusing point. Within the third zone, which ranges from 400° to 1,000° for copper, and diminishes as the zinc increases, the alteration of the mechanical properties by annealing is sensibly the same. In all these cases, annealing causes a reduction in strength and an increase of elongation before rupture. Finally, at temperatures near to the fusing point of the alloy, the metal sometimes becomes burnt, and suffers in both strength and extensibility; the extent of this zone depends upon the presence of impurities, especially of fusible metals, such as lead and tin. 3. The tests of perfectly annealed brass, show that the tensile strength rises as the zinc increases, until it reaches a maximum at about 43 per cent. of Zn, whilst the extension at the moment of rupture increases simultaneously, but reaches its maximum at 30 per cent. of Zn; in each case the diminution is rapid after the highest point is attained. The most useful alloys, therefore, are those in which the percentage of zinc ranges between 39 and 43. The actual tests are as follows:—

Composition of Metal.		Cold-worked.		Perfectly Annealed.	
Cu.	Zn.	Tensile Strength.	Extension.	Tensile Strength.	Extension.
		Kilos.	Per Cent.	Kilos.	Per Cent.
100	0	34	0	21	33
90	10	37	0	24	37
80	20	42	0	25	42
70	30	50	0	31	66
60	40	57	0	37	39
50	50	10	0	9	2

—W. G. M.

Steel, Extra hard, the Quenching of. F. Osmond.

Comptes rend. 1895, **121**, 684—685.

THE polished surfaces of steel bars, carburised by cementation, and highly hardened by quenching, are capable of being scratched by a sewing-needle, if their carbon percentage is lower than 0.7 or higher than 1.3; but between these proportions the effect of the scratch is not traceable. In the most highly carburised specimens however, the scratch is shown by the microscope to be intermittent, and the steel must therefore contain at least two constituents, which may provisionally be termed A and B, of which the former is not scratched by the needle, but will itself scratch glass, whilst the latter is scratched by apatite and possibly by fluorspar. The colour of A on a well-polished surface is greyish, that of B is white. In spite of the difference in mineralogical hardness, polishing in bas-relief by means of moistened and rouged parchment does not cause any sensible depression of the surface of B. Etching by tincture of iodine or by dilute nitric acid shows that the mass is divided into polyhedra that are but slightly coherent, and may or may not be separated by traces of a carbide which is probably Fe₃C. But A and B assume different colours, usually identical for the same constituent, in the same polyhedron. A is generally distributed in the form of lamellae, parallel-barbed in two directions, which are constant for each polyhedron, whilst B forms the groundwork. Prolonged etching renders the whole section black, hence both constituents must be carburised. A is the hard material which constitutes practically the whole of quenched steel containing 1 per cent. of carbon. The proportion of B increases with the proportion of carbon up to 1.6 per cent., beyond which the carbide Fe₃C (?) appears in increasing quantity. With a steel containing 1.57 per cent. of carbon, the maximum of constituent B is obtained when the steel is heated to at least 1,000° C. (there is no gain in exceeding 1100°), and is then quenched as rapidly as possible, in ice water or in very cold mercury. Otherwise some Fe₃C separates and diminishes the proportion of carbon in the remainder of the mass to a corresponding extent. Under the most favourable circumstances a mixture of equal parts of A and B may be obtained. Such a mixture is but slightly magnetic as compared with the same material quenched at 800° C. in water at the normal temperature. The intensity of the residual magnetism in such a bar, quenched at 1,000° C. in ice water, was found to be 345 immediately, and 221 two days after magnetisation, whilst that of a bar, quenched at 800° C. in water at 15° C., was 966 and 814 under similar circumstances. Since A is known to be magnetic, it may be suspected that B is non-magnetic. The same mixture of A and B cannot be filed, and breaks without bending, as much because A is hard and brittle as because of the want of cohesion between the polyhedra; but it breaks down freely when it is crushed. The properties of B appear to resemble those of steel containing 25 per cent. of nickel or 12 to 13 per cent. of manganese, presenting no critical point during slow cooling, and containing the iron in the form naturally stable above 850° C. (γ-iron).—W. G. M.

Gold, Analysis of, from Batoum District. G. Tchernik.

J. Russ. Chem. Soc. 27, 492—496.

ONE specimen of gold analysed contained 65 per cent. of gold and 35 per cent. of palladium. Another sample contained 88.4 per cent. of gold and 11.6 per cent. of rhodium.

—J. W.

Copper, Action of Hydrochloric Acid on. R. Engel.

Comptes rend. **121**, 528—530.

THE decomposition of hydrochloric acid by copper is so slow that it is often overlooked, but in saturated solution at 15° C. it is decomposed sufficiently rapidly for the evolution of hydrogen to be demonstrated; if a little platinum chloride be added, the reaction becomes tumultuous. Hydrochloric acid of less density than 1.083, which corresponds to HCl + 10H₂O, is without action on copper, and the action becomes extremely slow at greater strengths when the liquid is saturated with cuprous chloride. From this it would appear that the hydrochloric acid necessary to

maintain the cuprous chloride in solution is incapable of reacting on the copper, and that the slow action that does take place is due to variations in temperature; a fall in temperature producing a deposition of cuprous chloride, leaving the liquid, when a rise takes place again, incompletely saturated and capable of slight action upon the copper. When a current of hydrochloric acid gas is passed into water containing copper and cuprous chloride, a rapid action takes place notwithstanding the presence of the copper salt.—J. G. W.

Nickel and Cobalt Silicides. Vigouroux. *Comptes rend.* 1895, **121**, 686–688.

METALLIC nickel or cobalt heated strongly with 10 per cent. of silicon in hydrogen gas, gives crystallised ingots, exceedingly hard and difficult to break, which consist of the silicide mixed with an excess of metal, that may be removed by treatment with very dilute nitric acid. The resulting crystals contain silica, from the partial attack of the acid upon the silicide. A mixture in the proportion of one atom of silicon to one molecule of the metal gives a pulverulent mass of silica, metallic oxide, and silicide, when heated in a Doulton crucible in a Deville's furnace. Dilute nitric or hydrofluoric acid separates the impurities with difficulty. The best results are obtained on treating a 10 per cent. mixture in the electric furnace; as the heating is continued, the excess of metal distils off, leaving the silicide at last nearly pure, but the duration of the experiment must be governed by the bulk of metal operated upon, for if continued over long, nothing would remain in the crucible. The ingot obtained is greyish-white, and very hard and brittle. After cleaning the surface, the ingot is broken into fragments, and treated with very dilute nitric acid, to remove the trace of residual uncombined metal. The pure residue is a silicide with the formula SiNi_2 or SiCo_2 . These silicides are steel-grey, crystalline, and metallic in appearance; they are more fusible than either of the constituents, and resist the highest temperatures without decomposition. The density of nickel silicide is 7.2 at 17°, and that of the cobalt compound 7.1. The silicides burn in fluorine at the ordinary temperature, with the formation of white fumes of fluoride of silicon; in chlorine they burn at a red heat, but bromine and iodine have a less violent action. Oxygen (or air) attacks them also at a red heat, especially if they have previously been pulverised. Dry hydrofluoric acid gas, passed over the silicides contained in a platinum tube heated to redness, attacks them, yielding a combustible gas. Dry hydrochloric, hydrobromic, or hydriodic acid gas acts slowly at a red heat, giving metallic haloid compounds and gases which yield silica and hydrogen when led into water. Hydrofluoric acid solutions attack them readily, the other acids but slowly. Aqua regia completely decomposes the powdered crystals. Alkalis in solution are without action, but their carbonates, when fused, decompose them at a red heat, yielding alkaline silicates and an insoluble oxide of nickel. Mixtures of carbonate and nitrate of potash behave similarly, but at a lower temperature. Cold water is without action, but steam at a red heat decomposes the silicides.

—W. G. M.

Aluminium Vessels. Bulland. *Comptes rend.* **121**, 381–383.

THE French War Office has ordered the use of aluminium drinking and mess vessels for the army, which are made without solder, being beaten up from plate.

Similar vessels, made in the same way from the same plate, vary in weight by from 4 to 9 per cent. of the total. The author attributes this to the solvent action of the soda baths which are used to clean the surface of the manufactured vessel.

The vessels resist well in ordinary use, mechanical wear and tear, and the action of fire, foods, and cooking liquids which are not in contact with the metal for long periods.

Water left in these vessels for some months gives rise to flocculent deposits of alumina. These seem always due to particles of foreign substances in the metal, and appear especially in the neighbourhood of the rivets which fasten the handles, and which are made of alloys of aluminium. The loss of weight in this way during six months was less

than 9.1 per cent. Sheets of aluminium used in the author's former researches, and bottled up with Seine water for four years, became covered with a hard skin, dissolved off by 1 per cent. sulphuric acid, leaving a bright surface, and causing a loss of weight of about 3 per cent.

Salt water, of 35 grms. to the litre, acted like ordinary water, but to a much greater extent. The rivets become loose, and the handles come off. Except where the nodules of alumina are, a blackish, rough skin forms, which sand will not bring off, but which yields to 24 hours' soaking in 1 per cent. sulphuric acid. The loss of weight in four months through corrosion by the salt water was about 0.6 per cent.

—J. T. D.

Titanium, Preparation and Properties of. H. Moissan. *Bull. Soc. Chim.* 1895, 959–965.

THE conclusions drawn from this paper are that, when an electric arc of varying intensity is caused to heat a mixture of titanic acid and carbon, there are produced successively the blue oxide of titanium, fused titanium nitride (Ti_2N_3), and either fused titanium or a crystallised carbide TiC . Titanium is the most refractory substance yet obtained in the electric furnace, being more infusible than vanadium, and far more so than molybdenum or zirconium. It has only been prepared in the electric furnace at temperatures above that at which its nitride is decomposed, and by means of a dynamo absorbing 100 h.p. As compared with the powder obtained by the action of the alkali metals upon fluoritanates, the fused titanium has far less affinity for nitrogen: reduced to powder, however, it burns in nitrogen gas at a temperature of 800°C. The general properties of titanium resemble those of the metalloids, and particularly silicon.—W. G. M.

PATENTS.

Compressing, Squeezing, or Squirting Heated Metals, Improvements in or connected with Means or Apparatus for. G. A. Dick, London. Eng. Pat. 23,172, Nov. 29, 1894.

THIS patent relates to the construction of moulds used for casting copper alloys and "squirting" therefrom, whilst in a plastic condition, wires, rods, or bars. Instead of a mould with a thick wall, which is liable to fracture through irregular heating, the mould consists of an inner cylinder with an internal parallel bore, open at both ends. The outside of this cylinder is slightly conical, and fits into a tubular casing inversely tapered. Round this again are placed comparatively thin concentric casings with annular spaces between them. These spaces are tightly rammed with a non-conducting material, such as granite in small pieces, and, by preference, mixed with a little borax. Outside the whole, is the wrought-iron or steel casing. A mould is thus produced which can withstand pressure and retain the heat, and which also is not liable to fracture, since a new inner cylinder can be easily replaced. The outside casing is mounted on trunnions, so that it can be

swung vertically or horizontally. In the former position, the lower end is closed with a plug, and the copper or alloy poured in. When plastic, it is swung round horizontally, the false bottom is replaced by a die, and a ram or plunger, preceded by a heated block, enters at the other end, and forces the metal through the die.—A. W.

Blast-Furnaces, Cupolas, Steel-melting or other Furnaces supplied with Hot or Cold Air, An Improved Tuyère, Block, and Plate Coil for Use in. J. Patterson, Workington. Eng. Pat. 23,502, Dec. 4, 1894.

A COPPER coil with a brass covering is substituted for the usual iron or steel coil with cast-iron covering; or an iron or steel coil may be lined (e.g., electrolytically) with copper or other metal of high conductivity, and covered with cast iron in the ordinary way.—W. G. M.

Gold and Silver, the Extraction of [Cyanide Process], from Ores, Improvements in or relating to Processes for. J. Pfleger, Kaiserslautern. Eng. Pat. 23,557, Dec. 4, 1894.

A VESSEL is employed with a porous partition of unglazed earthenware down the centre, dividing it into two compartments. On one side of the partition is placed the cyanide solution containing the gold, &c., whilst the other side is filled up with a solution of caustic soda of a strength of from 1 to 5 parts to 100 parts of water. In the soda solution is placed a rod of an electro-positive metal, such as iron, zinc, copper, or aluminium, and in the cyanide solution an electro-negative substance unacted on by cyanide, such as carbon. A current is set up by joining these two substances with a metallic wire outside the vessel, whereby the gold is deposited from solution on the carbon, and may be collected and refined in any suitable manner.

—A. W.

Gold, a Method for Extracting, without the Use of Water, by Means of a Combined Air Blast and Mercury, and Apparatus for effecting same. W. H. Hyatt, London. Eng. Pat. 24,782, Dec. 20, 1894.

THE dry pulverised gold-bearing material is blown by strong currents of air on to or through liquid mercury placed in suitable tubes, &c. The ore is blown through these tubes and the gold is stated to amalgamate with the mercury.

—A. W.

Precious Metals, Improvements in or relating to Apparatus employed in the Recovery of, from their Solutions. H. L. Sulman, London. Eng. Pat. 2729, Feb. 7, 1895.

THE apparatus consists of a storage tank for the zinc fume, the bottom of which slopes to a point where there is provided a tubular outlet containing a double valve, so that a given quantity of fume may be let through at a time. This valve is attached to a rod, which is connected with a lever arrangement working in conjunction with a ball and siphon tank supplying the gold solution. The solution is constantly fed into this tank, which alternately fills and empties. Every time the solution siphons off, the float ball in falling works the lever connecting the valve in the fume tank. By this means the required quantity of fume falls into the tubular channel through which the gold solution is rushing from the siphon. This mixture passes into a cylindrical or conical vessel, where it is swirled round and automatically siphoned into the top of a vessel containing inclined baffle plates one under the other, which further agitate the solution. The gold being thus separated from solution, it is collected together with the remainder of the fume by passing the mixture upwards over a series of inclined plates of slate placed close together, upon which the solid particles deposit, and from which they slide down into the bottom of the vessel, whilst the waste liquor passes out of the top and through a filtering cloth.—A. W.

Precious Metals, Improvements in or relating to the Precipitation of, from their Solutions [Cyanide Process]. H. L. Sulman, London. Eng. Pat. 2730, Feb. 7, 1895.

IN the author's process of precipitating the precious metals by means of zinc fume, it is advantageous to submit the

fume to a preliminary cleaning to free it from zinc oxide. It is therefore digested with any reagent that will dissolve the oxide; and ammonia, ammonium chloride, and ammonium carbonate are claimed for the purpose. The use of these solutions may also be applied to the cleaning of zinc shavings and granules used in other processes.—A. W.

Ores containing Zinc or Blende and other Metals and Metalloids; Improved Method or Process, and Apparatus for obtaining Chlorine and Zinc in the Treatment of. H. R. Lewis, London, and C. Gelstharp, Manchester. Eng. Pat. 584, Jan. 9, 1895.

THE ore is crushed and roasted in furnaces of the type protected by Eng. Pat. 6567 of 1892 (this Journal, 1893, 12, 842), sulphur, sulphuric acid, and volatile metallic compounds being recovered. The zinc in the roasted ore is dissolved by water or dilute acid, and a certain proportion of a soluble chloride is added, which depends upon the percentage of zinc present. The liquid (after settling, if necessary) is concentrated by evaporation, the residue being treated according to Eng. Pat. 8467 of 1892 (this Journal, 1893, 12, 765). The solution is electrolysed, the chlorine and zinc being recovered. The electrolytic vat is preferably divided up into separate compartments by the alternate anode plates, which may be of carbon, and cathode plates, which may be of zinc. Both electrodes may be of suitable metallic gauze, covered with asbestos. Within the compartments thus formed are series of transverse glass plates, placed obliquely, in such a way that ascending bubbles of chlorine are deflected upwards and away from the cathodes. Above each of these chambers, which is otherwise closed air-tight, is a tube leading upwards to a horizontal main for the collection of the chlorine from all the compartments. Scrapers are provided to remove the rough deposited zinc, and cocks or valves are arranged below to discharge it into trucks placed beneath them. Reguline, instead of pulverulent deposits, may be obtained. In another type of depositing apparatus, a circular round bottomed vessel is employed, with an outside heating chamber; a perforated cathode forms a false bottom to the former, and the anode is suspended above it, separated or not by a porous diaphragm; the chlorine is led off above, and the zinc, detached by a rotary scraper, falls through the perforations in the cathode, and is drawn away through a cock as before. In each apparatus, pipes are arranged for the conveyance of the electrolyte to the vats.—W. G. M.

Lead; Improvements in the Extraction of, with Silver, Gold, or other Metals from Ores blended with Sulphide of Zinc or otherwise. H. R. Angel, London. Eng. Pat. 801, Jan. 12, 1895.

SULPHIDE ores are treated in a furnace, V-shaped in cross section, but tilting endwise, with a slag outlet at one end and a metal tap-hole at the other, and with a separate chamber containing a coke fire at one side. The furnace is of iron plates, lined with firebrick cemented by a mixture of 90 per cent. of volcanic dust or fireclay, and 10 per cent. of iron oxide mixed to a cream with sodium silicate solution. The ore is to be mixed with caustic soda or sodium sulphide, and to be heated by driving a mixture of steam and petroleum, or of gas and air, over the coke fire and through apertures in the partition wall. The charge is said to be reduced in a few minutes.—W. G. M.

Alloys of Iron with other Metals [Manganese, Aluminium, Nickel, Chromium, Tungsten, &c.], Manufacture of. C. D. Abel, London. From M. M. Roiten, Berlin. Eng. Pat. 1155, Jan. 17, 1895.

THE metal to be alloyed with the iron is obtained in a finely-divided state, either as a powder if brittle, or as drillings if malleable; it is then mixed with lime and with coal or coke in sufficient quantity to produce the required carburization, much as described in Eng. Pat. 23,286 of 1892. The mixture is moistened with water, moulded and compressed, the blocks being heated to drive off the hygroscopic, but not the combined water. The pieces thus prepared are then introduced into the iron in the ladle, in the furnace, or otherwise. The hydration water,

which is evolved as vapour, serves to mix the metals, whilst it is considered to expel gases from solution in the liquid metal. Other alkaline earths or alkaloids may be used instead of lime; and in place of the metal to be alloyed, its oxide may be employed, mixed with a sufficient excess of carbon. The process is especially applicable for use with manganese, aluminium, nickel, chromium, and tungsten.—W. G. M.

Metals and Metallic Alloys containing Carbon and Silicon: Process for the Production of. W. Kaufmann, Prague. Eng. Pat. 2278, Feb. 1, 1895.

CARBONUM IN a finely-divided state is added at a high temperature to the molten metals which are required to be combined with carbon and silicon. An electric furnace is employed by preference.—W. G. M.

Metals and Metallic Compounds: Improvements in their Recovery from Finely-divided Substances, such as Crushed Ores, Slime, Tailings, and the like. G. Robson, Dolgelly, and S. Crowder, London. Eng. Pat. 2538, Feb. 5, 1895.

IN carrying into effect Eng. Pat. 427 of 1894 (this Journal, 1895, 14, 580), soap and water of the consistency of white of egg, with hydrocarbon oil, may be substituted for the mixture of fatty and hydrocarbon oil previously specified. The dry finely-divided substances also may be prepared for treatment by first moistening them with a liquid hydrocarbon and a fatty oil, and then adding the necessary quantity of water.—W. G. M.

Casting Copper Ingots, A New or Improved Solution [to Prevent Adherence] for Use with Moulds for, or the like. J. Lunt, Warrington. Eng. Pat. 13,617, July 16, 1895.

THE bark of the oak or other suitable tree is calcined "together with a proportion of valonia," and the ashes so produced are, after being cleaned, powdered, and mixed with water, used as a wash for moulds in the preparation of copper castings. Spent oak-bark, and valonia which has been employed in the tanning process, are preferably employed, the proportions being about equal. The effect of the above treatment is to produce a wash which will prevent the copper adhering to the mould.—A. W.

Ores and other Auriferous Substances, Improved Process [Bromine and Chlorine] and Apparatus for Extracting Gold from. B. C. Hinman, New York, U.S.A. Eng. Pat. 16,920, Sept. 10, 1895.

THE object of this invention is to use an excess of bromine for gold extraction, by which means the dissolving is accelerated, and to regenerate the bromine. The pulverised ore mixed with water is treated in a revolving cylinder with from 3 lb. to 20 lb. of bromine per ton of ore, and the solution thus obtained, drained off. The ore is leached, preferably with chlorine water, which is then added in a closed tank to the bromine and bromide solution. More chlorine may be introduced into this mixture to decompose the bromides if necessary. The tank and its contents are heated in any convenient way, preferably by steam, and the bromine distils off through a pipe leading from the top of the tank to a condenser. The gold is recovered from the residual chloride solution in the usual manner.—A. W.

Amalgamation of Gold and the like Metals in Ores, An Improved Process for Effecting. E. L. Oppermann, E. Fischer, and C. T. J. Oppermann, all of London. Eng. Pat. 17,020, Sept. 12, 1895.

TO ensure the complete amalgamation of the gold, including the fine and float gold, the wet or dry crushed ore is brought into contact with mercury vapour at a suitable temperature. The vapour is conveyed by pipes from the retort in which the mercury is heated, and is blown on to the crushed ore, or even made to pass through a perforated plate over which the ore is passed. The vapour may be mixed with steam or other suitable gas, and any convenient means may be used to recover the gold from the amalgam which is said to be obtained.—A. W.

Gold and Silver, Process [Bromine and Chlorine] and Apparatus for the Extraction of, from their Ores, and from other Auriferous and Argentiferous Substances. H. A. de Neufville, Paris. Eng. Pat. 18,177, Sept. 28, 1895.

THE pulverised material or ore, mixed with water, is introduced into the apparatus, and the following reagents added in small quantities, which vary according to the nature of the material under treatment, viz., bromine or one of its compounds, sodium chloride or hydrochloric acid, potassium cyanide, a plate of copper connected with the anode to secure the solution of a little copper, mercury or its amalgam similarly connected for the same purpose, sulphuric acid to render the solution acid, and sulphates of iron and copper to assist the formation of complex salts. Electricity is used in conjunction with this mixture, thereby producing chlorine, bromine, and chloride of bromine, which dissolves out the gold. The sulphuric acid is used for facilitating the action by the production of hypochlorites and the liberation of chlorine by electrolysis, whilst the cyanide is employed to scour the surface of the mercury. The apparatus consists of a cylindrical tank with a central revolving vertical rod, which carries small blocks of retort carbon for agitating the solution. Inside this tank are placed a series of concentric plates, alternately connected with the positive and negative poles of a dynamo. Those forming the anode are made of retort carbon, and are perforated, whilst the cathode plates are amalgamated metal. A thin layer of mercury is also placed at the bottom of the tank, and is negatively connected. Suitable outlets are arranged for the gold amalgam obtained and for the ore residues from which the gold has been extracted, the whole process being conducted in one vessel.—A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

A Cell of High and Constant E.M.F. M. Marisot, L'Éclairage Électrique, 1895, 4, 297; Comptes rend. 1895, 121, 251.

THE cell is prepared in the following manner:—The positive pole is a plate of retort carbon, placed in the outer jar, containing a depolarising liquid, prepared by mixing 3 vols. of a saturated solution of bichromate of potassium with 1 vol. of sulphuric acid. Crystals of bichromate are added to keep the solution saturated. A porous pot immersed in the depolarising liquid contains a solution of sodium hydrate of sp. gr. 1.05. The negative pole, consisting of a plate of amalgamated zinc, is placed in a second porous pot within the first, and contains a solution of sodium hydrate of sp. gr. 1.25.

THE author states that the E.M.F. of this cell is 2.5 volts at the start, and keeps above 2.4 volts during 10 hours of uninterrupted work. The internal resistance is about 0.8 ohm, but this value varies with the nature and thickness of the porous pots. In a cell containing 600 c.c. of depolarising liquid, 130 c.c. of weak and 110 c.c. of concentrated sodium hydrate, a current of 0.432 ampère was maintained through a resistance of 5 ohms, and one of 0.220 ampère through 10 ohms.

UNDER these conditions the intensity is maintained as stated. The regular régime is established in something short of an hour, when the diaphragms are sufficiently impregnated.

THE increase of voltage over the ordinary bichromate cell arises from the substitution of the alkaline for the acid solution usually surrounding the zinc. The advantage obtained by this substitution alone is small, owing to the rapid increase of resistance. The sodium hydrate is converted into a neutral chromate, and an abundant deposit of zinc hydroxide is found on the zinc. This action is, however, lessened by the interposition of the weak alkaline solution. The use of potassium instead of sodium hydrate does not offer any advantage, neither does that of bichromate

of sodium instead of bichromate of potassium in the depolarising liquid. After 10 hours of continuous action the zinc becomes covered with a grey coating, which may be removed by dipping it into dilute acid, when the cell will be again in working order.—J. L. B.

PATENTS.

Carbides, and Illuminating Gas derived therefrom, Improvements in the Production of Metallic. G. B. Ellis, London. From T. L. Willson, New York, U.S.A. Eng. Pat. 16,342, Aug. 27, 1894.

See under II., page 103.

Galvanic Cells, Improvements in the Construction of. C. Vogt, Posen, Germany. Eng. Pat. 16,586, Sept. 1, 1894.

THE improved cell, which can be used either as a dry or as a wet element, is constructed as follows:—A zinc and a carbon electrode are placed with water in a suitable vessel, and metallic oxides (preferably the peroxides of lead or manganese) which have been saturated with chlorine either by mechanical or electrolytic means, are pressed into the surface of the carbon. A dark cell is employed in order to prevent the formation of hydrochloric acid by the combination of the hydrogen from the water with the chlorine; and as soon as the current is passed, the electrolysis gradually effects a separation between the oxygen and the metallic oxides by the substitution thereof of chlorine, whilst the water is decomposed into hydrogen and oxygen, and the oxygen, which combines with the zinc electrode, is continually replaced by the oxygen freed from the metallic oxides. It is claimed that by using more chlorine, or oxides richer in oxygen, that the voltage can be raised to 2.20 volts.—G. H. R.

Electrolysis, Method of and Apparatus for Effecting. C. Kellner, Vienna, Austria. Eng. Pat. 24,541, Dec. 17, 1894.

IN the apparatus described, a cylinder is employed composed of porcelain or stoneware, provided with numerous helical channels, through which the mercury flows in the form of a stream, the parts of the mercury stream in the several channels constituting strips. The channels are arranged so that the odd-numbered convolutions of the helix are on the inner surface of the cylinder, whilst the even-numbered ones are on the outside. The internal channels in the decomposing cell communicate with the external ones in the forming cell by means of openings in the walls of the cylinder. Within this is placed a cylindrical anode filled with the solid salt to be decomposed, and is so arranged that the salt cannot enter the mercury channels, but passes from below the anode into the electrolyte. The whole is placed in a covered iron vessel, which contains the water or other reagent with which the separated cation is to be combined. The mercury is supplied to the topmost channel by means of a pipe, and is connected at various points of its course with the iron-containing vessel, to which the lead from the negative pole of the dynamo is attached. If the combination of the cation with the reagent is to be utilised as a source of energy, another lead connects the mercury in the combining vessel with the negative pole of the dynamo.—G. H. R.

Secondary Batteries, Improvements in. C. A. Faure, Paris, and F. Kiog, London. Eng. Pat. 1731, Jan. 24, 1895.

THE improvement consists in constructing the plates for secondary batteries of a light metallic support, which is coated with active material, and, to prevent loss from the falling away of this, the plate is surrounded or coated by a thin layer of silicated asbestos fibre, cloth, or paper, and upon or around the plate so covered, a perforated envelope of celluloid, ebonite, or other acid-resisting, non-conducting material is placed.—G. H. R.

Cables, Improved Insulating Material for, and Process of Making Same. A. Gentzsch, E. R. von Scanavi, and N. R. von Scanavi, Vienna. Eng. Pat. 5967, May 6, 1895.

THE new insulating material consists of one or other of the minerals of the species hornblende, from which the water

of crystallisation has been driven off by heat. The mineral may be used alone, or mixed with other insulating material, such as rubber. In the latter case, good results are obtained by using 10 per cent. of the hornblende mineral and 90 per cent. of rubber. The materials are mixed hot, when the rubber penetrates the mineral, which is in a porous condition, owing to the expulsion of the water of crystallisation.—V. C.

Insulators for Electrical Purposes, Improvements in and relating to. A. J. P. Whitaker and F. G. Treharne, Llanishen, Cardiff. Eng. Pat. 11,528, June 13, 1895.

THE improved insulators, which are chiefly for telegraph and telephone wires, consist of a metal shell coated with a non-conducting enamel, in combination with a spindle for carrying the insulator. The spindle is secured by insulating cement.

The non-conducting enamel is composed of "silica, aluminium, barium, oxide of tin, and borax."

The insulating cement is composed of sulphur, bitumen, sulphate of lime, or of barium, silica, and oxide of lead or resin.

The improved insulators are adapted for use in any climate, and are practically unbreakable.—V. C.

Vegetable Parchment, Improvements in Treating, to make it applicable as an Electric Insulating Material, and for other Purposes. J. A. London and H. P. Bailey, Newcastle-on-Tyne. Eng. Pat. 12,711, July 2, 1895.

See under XIX., page 132.

Electrodes, Improvements in and appertaining to. H. Leitner and E. Reicher, Nieder-Schönhausen, Germany. Eng. Pat. 18,038, Sept. 26, 1895.

THE improved outer electrode is composed of lead peroxide and carbon prepared in tubular form in such a manner that the outside consists of a firm mass of carbon, whilst the peroxide of lead is on the inside, and is made conducting by an admixture of carbon dust. The peroxide of lead is forced into the carbon plate under pressure, and penetrates its pores to the depth of several millimetres. The electrode thus prepared is surrounded by a coating of insulating material, such as celluloid or ambrion (Eng. Pat. 14,334, 1895), which also forms a bottom to it, thus converting it into a cell capable of containing the sulphuric acid. The inner electrode consists of a staff of vulcanite supporting a lead tube on which chemically pure zinc is precipitated.—G. H. R.

Double-Fluid Galvanic Batteries, Improvements in. E. S. Boynton, Brooklyn, U.S.A. Eng. Pat. 20,215, Oct. 26, 1895.

THE battery consists of two or more cells of the Daniell type, which are placed in a reservoir containing a solution of copper sulphate. The cells are set up with the zincs in the zinc sulphate solution in the porous pots, whilst the copper plates are in the outer jars, which are perforated down one side to admit of the circulation of the copper sulphate solution.—G. H. R.

Galvanic Batteries, Improvements in. E. S. Boynton, Brooklyn, U.S.A. Eng. Pat. 20,216, Oct. 26, 1895.

IN the improved battery the electrolyte is common to all the elements, which are arranged so that one electrode of each element is separated by insulating material from the corresponding electrode of the adjacent element, so that the full voltage due to the number of the elements is attained. Each pair of zinc and carbon plates forming an element is surrounded by an open-bottomed casing of insulating material. The plates are suspended from the cover of the casing or cell, and the carbon does not extend to the bottom. When these cells are immersed in the receptacle, they rest on a perforated false bottom, which allows of the free circulation of the electrolyte to all the cells.—G. H. R.

Secondary Batteries, Improvements in. J. J. Rooney, Brooklyn, U.S.A. Eng. Pat. 20,431, Oct. 29, 1895.

THE improved plates are formed of insulating material perforated in vertical parallel rows, the grid having exten-

sions in the line of alternate rows to form foot-rests. The perforations are filled with active material, and the rows of plugs are alternately positive and negative, each row being connected to a conductor.

The material employed for the grid is preferably compressed paper, like press-board, which is perforated and treated with caustic soda and hydrochloric acid so as to reduce it to vegetable fibre, and remove all size and glue.

—G. H. R.

(B).—ELECTRO-METALLURGY.

Galvanising of Iron Electrolytically. O. Vogel, Diogler's Polyt. J. 1895, 298, 191—192. Paper read at the Oct. Meeting (1895) of the Eisenhütte Düsseldorf.

PRACTICALLY the three processes employed for the electro-deposition of zinc on iron are those of Cowper-Coles, worked by Messrs. Watson, Laidlaw, and Co. in Glasgow, and consisting of cleansing the iron in hot potash, pickling in sulphuric acid, washing, and then coating it with the aid of a dynamo yielding 2,500 amperes at a pressure of 5 volts; Richter's process, worked at Witkowitz (*Stahl u. Eisen*, 906); and Alexander's, which combines the methods of Schaag and Falk, and is worked by Seelhorst and Werner in Rothenfeld, Hanover, for the deposition of zinc containing aluminium or magnesium. The advantages of the galvanic as compared with the fusion method of galvanising are summed up in stating that it gives a more uniform and a thinner coating, which is nevertheless perfectly protective, whilst it eliminates the loss due to the formation of hard zinc and dross, is applicable to complex forms, and does not require continuous work. On the other hand, it demands a larger number of, and more intelligent, workmen, whilst it requires more time, and is therefore unsuitable for large-scale operations. For the treatment of 10,000 kilos. of sheet daily, a space of 200 sq. m. area would be necessary, and the plant, excluding a 50- to 60-h.p. engine, would cost about 27,000 M. In the discussion, Eckardt, speaking of the Richter process, described it as ill adapted for work on a large scale, and doubted whether the galvanised surface could ever be faultless, on account of the difficulty in rendering it quite clean. Seelhorst (of Seelhorst and Werner) uses the sand-blast with advantage for cleansing, and finds that the cost of their process works out at 5 pf. per sq. m. of plate, as against 50—60 pf. by the fusion method. Schmidt considered that the galvanic process could not well be applied to the treatment of telegraph wire, because the resulting product would not stand the immersion test (immersion in copper sulphate solution eight times repeated).—W. G. M.

PATENT.

Tin, Electrolytic Treatment of, and its Separation from Alloys and Mechanical Mixtures, Improvements in. C. F. Claus, junr., Swansea, and H. S. Sutton, Neath, Wales. Eng. Pat. 297, Jan. 4, 1895.

THE improved process for recovering tin from alloys or coated materials such as "scrap tin" consists in making them the anode in an alkaline sulphide bath, preferably composed of 1 part sulpho-stannate of sodium, and 2 parts of water, yielding a solution of sp. gr. 1.070, which is heated to approximately 90° C. The cathode is preferably formed of tin, and with a current density of 10 amperes per square foot of anode surface, the tin is deposited in a metallic state upon the cathode, and may be recovered therefrom in any suitable manner. In the event of the deposited tin containing either antimony or arsenic or both,

it may be used as an anode in a bath of sufficiently diluted hydrochloric acid, to which hyposulphite of soda (thiosulphate) is added as required. The bath is provided with a tin cathode as before, and by the passage of the current the arsenic and antimony are precipitated as sulphides, whilst the tin is deposited on the cathode.—G. H. R.

Gold and Silver, Process and Apparatus for the Extraction of, from their Ores, and from other Auriferous and Argentiferous Substances. H. A. de Neufville, Paris. Eng. Pat. 18,177, Sept. 28, 1895.

See under X., page 120.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Lubricating Oil Testing, Recent Experiences in. Holde. Mitt. aus d. königl. techn. Versuchsanstalt zu Berlin, 13, (6), 253.

See under XXIII., page 138.

Rape Oil and other Vegetable Oils, The Congealing Points of. D. Holde and A. Ruhemann. Mitt. aus d. Königl. techn. Versuchsanstalt zu Berlin, 13 (6), 287—290.

The congealing points of the various kinds of rape oil range between—

°C.	°C.	
—2	and —10	for colza oil (Benedikt).
—1	" —10	" Brassica campestris (Bornemann).
—6.3	"	(Girard).
—4	"	" colza oil (Hübl).
—4	" —6	" Brassica campestris (Schädler).
—8	" —10	" rapa (summer) "
—4	" —7.5	" " (winter) "
—1	" —4	" napus (summer) "
—1	" —3	" " (winter) "

Black mustard oil congeals at —17.5°, according to Chateau, or —1° to 0°, according to Girard. For white mustard oil Bornemann gives —16° and Schädler —8° to —16°.

From the tabulated results of tests made at Charlottenburg it would appear that nearly all rape oils will congeal at about 0° after standing for 8 hours. The lower temperatures recorded by other observers, probably refer to oils that have been simply exposed to cold without being stirred, this latter operation assisting solidification.

Olive oils, by reason of their varying content of stearin, congeal at different temperatures; an oil from Bari, for example, being found completely set after 5 hours' exposure at 0°, whereas a Rizza oil still remained fluid, though very turbid, after standing for 4½ hours at —8° C. Arachis oil, on the other hand, assumed a salvy consistency in 4 hours at 0°, and set like tallow in three-quarters of an hour at —5° C.—C. S.

Oils for Greasing Wool. A. Merstone. Chem. Rev. Fett u. Harz Ind. 1895, [29], 1—2.

FOR this purpose, neutral oils, mixtures of soap with neutral fats and fatty acids, and emulsions of oil with water are employed, the chief essentials being easy removal by washing and freedom from oxidisable and mineral oils, on account of the liability to spontaneous combustion of the wool induced by the former, as well as of the streakiness occasioned by both in the dyed wool. At one time olive oil alone was used, but was superseded by oleic acid, and later by the "extract oil" from recovered grease, which now frequently contains from 20 to 30 per cent. of mineral oil. The emulsions of "soluble" oils allow the oil to be more regularly distributed on the fibre, but spinners are apt to abuse this capacity for mixing with water and to dilute them to excess, with unfavourable results. Some "soluble" oils sold as pure olive oil contain 88 per cent. of water and 12 per cent. of rape oil, or mixed mineral and seed oils. The composition of some others is given below:—

"Olive" Oil.—Olive oil, 30 per cent.; rape oil (treated with oil of rosemary), 70 per cent.

"*Olein*."—Fatty acids, 36; mineral oil, 64 per cent.

"*Extract*" Oil.—1. Fatty acids, 91; mineral oil, 5; dirt and water, 1 per cent.

11. Fatty acids, 65; mineral oil, 24; neutral fat, 9; dirt and water, 2 per cent.

"*Soluble*" Oils.—Fatty acids or neutral oils holding ammonia soaps in solution, with or without resin.—C. S.

Cholesterols of Cryptogams. E. Gérard. *Comptes rend.* 121, 723–726.

By extracting brewers' yeast, the mould, *Mucor Mucedo*, and the lichen, *Lobaria pulmonacea*, with alcohol, evaporating the extract and again extracting with ether, the author has in each case obtained a fatty substance which, when freed from fat, yielded a body which agreed in properties with a cholesterol of the ergosterin group. The cholesterol contained in the cryptogams are therefore distinct from animal cholesterol and from phytosterol, the cholesterol of the higher plants.

The author gives the following additional reactions which serve to differentiate animal cholesterol from cholesterol of the ergosterin group:—1. Animal cholesterol treated with concentrated sulphuric acid gives a yellowish coloration, the addition of water producing a white precipitate. Ergosterin, on the contrary, gives a red coloration, and with water yields a green precipitate. 2. The addition of sulphuric acid of 1.76 density to a solution of animal cholesterol in carbon tetrachloride gives a yellow coloration, which changes to milk-white in the presence of water. When left to stand the tetrachloride which separates out is colourless. Ergosterin and the analogous cholesterols, treated in the same manner, yield a blood-red coloration, and the tetrachloride which separates is coloured green.—J. G. W.

Oils or Fatty Substances, Improved Method of Recovering from Clays, Sands, Ores, Mine Slimes, or other Finely-divided Substances. S. Crowder, London. Eng. Pat. 23,228, Nov. 30, 1894.

The mixture of the finely-divided substances and water is introduced into a suitable vessel, so as to produce an upward current. As the oil rises to the surface it is allowed to flow over the edge into receptacles at the side of the tank, or is skimmed off by means of revolving brushes or paddles. The separation of the oil is facilitated by blowing a current of air through the mixture.—C. A. M.

Treatment or Oxidation of Fixed Oils, Fats, and the like, Improvements in, and the Application thereof as a Menstruum for Paint, Varnish, Oil-Cloth, and the like. S. Banner, Liverpool. Eng. Pat. 24,103, Dec. 11, 1894.

On blowing oil with air or oxygen in the usual manner, a point is soon reached where the varnish becomes insoluble in turpentine, &c., being therefore useless for the manufacture of paint. To avoid this, and also to enable the oxidation to be carried still further, the inventor adds to the oil, either before or during the operation, sufficient volatile solvent such as a paraffin or terpene, to keep it liquid, the temperature being so regulated as to prevent the volatilisation of the said solvent. The ordinary driers may be employed as usual.—F. H. L.

Drying-Oils, Treatment of. E. Andreoli, Brixton. Eng. Pat. 25,324, Dec. 31, 1894. (Date claimed under Inter. Conv. July 20, 1894.)

OZONISED air, prepared as described in Eng. Pats. 21,794, 1892, and 21,707, 1893 (this Journal, 1893, 452, and 1894,

162), is made to pass through or over the oil, which has been previously purified by treatment with 0.02 per cent. of tannin. The oxidation may be hastened by the addition of 0.25 per cent. of any hydrocarbon boiling above 100 °C. or other substance, such as tallow, "possessing great affinity for oxygen." The oil may also be made to pass over a series of glass plates stacked between the pointed grids of the ozonisers described *loc. cit.* and in Eng. Pats. 17,426, 1891, and 9631, 1892, being afterwards collected by scraping or otherwise.—F. H. L.

Waste Oil, Improvements in Apparatus for the Recovery and Purification of. V. Camiz and A. Bettoni, Venice. Eng. Pat. 11,948, June 19, 1895.

This apparatus consists of three parts working automatically—a recuperator for the recovery of oil which has been used for lubricating machinery, a separator, and a filter. These parts may either be arranged to work together, or may be set up separately.—C. A. M.

Oil from Vegetable Seed, Improvements in the Process of Extracting. H. T. C. Kraus, Brooklyn, New York. Eng. Pat. 20,107, Oct. 25, 1895.

The crushed seeds are first soaked with running water in a trough, and at the same time (*i.e.*, under water) subjected to the action of an agitator. The lighter hull is carried into a trough, while the kernels pass through a discharge-pipe into the tub of an agitator. Here they are mixed with more water, or with oil, acids, or alkalis, and reduced to a paste-like condition, which renders them "more susceptible or sensible for the evaporation." Thence they are conveyed in trays, by means of a carrier, into a boiler, to be subjected to the action of steam heat, dry or saturated, but preferably the former. The evaporated liquid is condensed by a worm, and falls into a tank, the fatty matter being on the surface. To clear and refine this, it is placed in pans in a jacketed boiler, and subjected to the indirect heat of superheated steam. The evaporated liquid passes into a chamber fitted with a series of perforated plates or wire gauze, and surrounded by a heating chamber. The more volatile matter passes on through a condenser into a tank, while the heavy oils remain in a recess at the bottom of the chamber, whence it can be removed by means of a tap. If necessary, the volatile matter left in the chamber with the heavy oils can be driven forward by the admission of superheated steam of low temperature.—C. A. M.

Oil Extracted by Solvent from Linseed or Similar Substances, Improvements in Purifying. The Cleveland Linseed Oil Company, Ohio, America. Eng. Pat. 23,166, Dec. 3, 1895.

The naphtha or other solvent is removed from the oil by the introduction of steam at a temperature of about or below 140 °F. By this means the coagulation of albuminoid matters in the oil is said to be largely avoided, which is one of the principal objections to the process of steaming as ordinarily practised. To this coagulation it is to be attributed, it is said, the unfitness of solvent-extracted oil for certain industrial uses, such as painting. Low-tension steam is obtained by delivering it from an ordinary boiler below the surface of the oil in the separator, the vapour pressure in the latter having been suitably reduced. The pipe employed to convey the steam below the oil has a bore of sufficient size to deliver enough steam without unduly raising the vapour pressure. The temperature of the steam will be low in correspondence with the reduced tension.

Practically, the operation is best carried out in two stages, the temperature being raised and a greater volume of steam introduced when the solvent has been largely removed.—C. A. M.

The New Rubber Plant (Kikxia Africana, Benth.).

"Kew Bulletin," No. 106, through Imperial Institute Journal (Research Dept.), February 1896, 56.

In his report on the Botanic Station at Lagos for the quarter ending 31st December 1894, the curator stated that the rubber industry of the colony was rapidly extending, and that the rubber supply of West Africa was not confined to species of *Landolphia* and *Ficus*, but that a large tree, probably belonging to the *Apocynaceae*, and occurring abundantly in the interior lands, and called by the natives *Ire*, *Irch*, or *Erch*, also yielded rubber.

Mr. Olubi, F.R.G.S., describes it as one of the most beautiful trees in the forest, growing to a height of 60 to 70 ft. It was first discovered in Acra about 1883, and many fortunes have been since made from the rubber it has produced. In the rainy season, when the trees are full of milk, a tree well tapped is capable of yielding 10 to 15 lb. of rubber.

The new rubber tree appears to be *Kikxia Africana*, Benth., belonging to the *Apocynaceae*. Its seeds were used in commerce as an adulterant of *Strophanthus* seeds. A sample of these seeds had been sent by Messrs. Bowden, of Liverpool, to Kew in 1888, under the name of *India-rubber seeds*; they came from Winnebah, Gold Coast, West Africa. The tree is evidently very widely distributed in the country, extending from Sierra Leone to the Gold Coast, and beyond the mouths of the Niger to the Bight of Biafra. How far its growth extends inland is at present unknown.

Mr. F. C. R. Leigh, acting curator of the Botanic Station at Lagos, states that, in tapping the *Ire* trees, a vertical cut is first made in the bark from the bottom to the top of the tree, $\frac{1}{2}$ to $\frac{3}{4}$ of an inch in breadth, and deep enough to reach the inner bark. On each side of this main-groove, two series of oblique grooves are cut, 2 ft. apart, each running into the main-groove, by which the milk exuding from the grooves is conducted to the base of the tree, where it is collected.

The methods adopted for coagulating the milk are at present of two kinds, viz.: the "cold process" and the "hot process"; the first-named chiefly practised by the Fanti men introduced from the Gold Coast. A cavity excavated in the trunk of a fallen tree, of sufficient capacity for holding the material collected during several days, is filled with the milk, which is first strained. It is then covered with palm leaves and left for 12 to 14 days or longer, according to the season, until most of the water has either evaporated or been absorbed by the wood. The rubber thus obtained, after being kneaded and pressed together, has a dark-brownish colour, the interior being slightly lighter in colour. Such rubber is known locally as "silk rubber." The local price is from 10d. to 1s. 2d. per lb.

The hot process, which deals with the milk daily as collected, is the one generally adopted by the natives of Lagos. The strained liquid is heated in a vessel, when the rubber begins to coagulate almost directly. After boiling, the product thus obtained is somewhat sticky, and of a blackish colour; its local price is from 9d. to 1s. per lb., the quality of the rubber being deteriorated by the crude character of the heating operation, which could easily be improved. An experiment in this direction was tried at the Botanic Station, and a product obtained similar to that furnished by the cold process. A sample of this, received at Kew, was reported to be of very fine quality, and rubber, if supplied in the same clean and dry condition, would realise 2s. 3d. to 2s. 4d. per lb.

Owing to the climbing habit of the species of *Landolphia* which have hitherto yielded African rubber, it has not been practicable to cultivate them in regular plantations, as they required the support of other plants, and when once they had been tapped, many years would have to elapse before they would be fit to yield another crop. With the *Kikxia* these practical difficulties disappear.

As showing the remarkable development which has taken place in the rubber industry at Lagos during the last six months, the Acting-Governor has furnished Kew with the following particulars:—

Return of Rubber exported from Lagos during the Half-Year ended June 30th, 1895.

PATENTS.

Nitrocellulose or Pyroxylic Compounds, Improvements in and connected with the Manufacture of. F. Greening, Stoke Newington. Eng. Pat. 22,019, Nov. 11, 1894.

THIS invention relates to the manufacture of nitrocellulose or pyroxylin compounds, and of a solvent therefor, for use as substitutes for ivory, india-rubber, vulcanite, &c.

Fibrous substances are immersed in a bath of sulphate of alumina and a bleaching agent, at 212° F. The fibrous substance is taken out, dried, and placed in a bath of a mixture of concentrated sulphuric and nitric acids. The saturated mass is then submitted to pressure to expel any excess of acid, and allowed to remain two or three hours, when it will be in a soluble condition.

It is then washed in a bath of sulphate of alumina and then with water, until all trace of the acid is expelled. It is afterwards dried, and is ready to be converted into a plastic or liquid substance by means of a suitable solvent.

The solvent is obtained from the distillation of wood-tar ("picamar"). This "picamar" is sometimes mixed with methylated alcohol and chromic acid salt and distilled, the distillate thus obtained being also suitable as a solvent for pyroxylin.—S. P. E.

A Substitute for India-Rubber, Gutta-Percha, and Substances of a Like Nature, and Process for Manufacturing the same. E. Hornung, Vienna. Eng. Pat. 20,243, Oct. 26, 1895.

This consists of glue or a glue substitute precipitated from its aqueous solution by means of tannin, &c., mixed with five or more per cent. of rubber, &c., and dried, with or without the addition of pulverised cork or other solid body, and softened, if necessary, with fats or glycerin.—F. H. L.

PATENT.

Tanning, An Improvement in. M. Lewin, Falkenberg, Germany. Eng. Pat. 20,123, Oct. 25, 1895.

The employment of concentrated liquors in the so-called quick-tanning process has the disadvantage that it causes the grain to contract and become drawn, producing unsightly leather. By the present invention the grain is protected by a preliminary treatment, consisting in squeezing off the skins whilst in the soft state, in which they are after they have been placed in a weak liquor and swelled, and impregnating them on the grain side with grease or oil. Such prepared skins will withstand the strongest liquors, even when warm, without damage to the grain.—A. G. B.

XV.—MANURES, Etc.

Calcium Cyanate, A New Nitrogenous Manure. C. Faure. Comptes rend. 1895, 121, 463.

CALCIUM cyanate may be expected to supersede sodium nitrate as a nitrogenous manure, being even richer in nitrogen than is the nitrate. The compound is made in an electric blast-furnace. A mixture of lime and coal is first directly heated in this furnace to 1,500° C., and then superheated electrically to 2,500° C. in the presence of a large excess of pure nitrogen. Finally, air is admitted, whereby the product is oxidised, and the atmospheric nitrogen, heated by the exothermic reaction, obtained sufficiently pure for introduction into the electrically heated sphere of action.

The author has no doubt concerning the assimilability by plants of the nitrogen of this compound.—A. G. B.

Manure and Preservatives and Disinfectants for Manure, Improvements in the Manufacture of. L. Tralls, Turn, near Teplitz, Bohemia, and E. Burmeister, Hamburg, Germany. Eng. Pat. 21,627, Nov. 11, 1895.

ASHES of fuels of all kinds are treated with dilute sulphuric acid (5°–10° B.), about 50 per cent. of acid serving to combine with the bases of household ashes from brown coal. The product is rapidly dried in air, but its desiccation may be hastened by heat; when dry, it forms a powder which remains dry in air, and is, therefore, easily strewn or otherwise distributed. These "sulphate ashes" are applied as manure, or as preservatives of manure. Thus, when mixed with stable dung or liquid manures, they fix the ammonia and prevent fermentation of nitrogenous materials. As a disinfectant and deodoriser, the sulphate ashes can be used in sinks, drains, sewers, and closets.

—A. G. B.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar-Cane Juice, Non-Sugar Constituents of. Maxwell. Bull. Ass. Chim. 1895, 13, 371.

ALCOHOL precipitates considerable quantities of a gum in evaporated cane-juice that has been boiled to coagulate the albuminoids. The author considers it to be a cellulose gum, which is easily, and sometimes with difficulty, hydrolysable by acids into hexoses and pentoses, glucose alone being obtained in a crystalline condition. 1.2 to 1.3 per cent. of the dry substance of the juice consists of nitrogenous bodies; 0.3 to 0.4 per cent. are albuminoids, partially coagulable; the remaining 0.9 per cent. are amides and amino acids.

CrySTALLISED asparagin and aspartic acid were obtained from the young shoots of the cane.—J. L. B.

Sugar, Recovery of, from Impure Products such as Molasses, Plant Juices, &c. G. Kassner. Dingl. Polyt. J. 1895, 298, 65.

THE author describes in detail the different phases in his process for the recovery of sugar, of which the following is a summary:—

1. Vigorous agitation of oxide of lead and water during the flowing in of the impure sugar solution; under certain conditions this operation is reversed, the oxide of lead and water being caused to flow into the agitated sugar solution.
2. Gentle warming to promote the formation of lead saccharate. If this takes place rapidly as it frequently does in concentrated solutions, a spontaneous evolution of heat is observed.
3. Allowing the semi-solid mass to stand until crystallisation is complete.
4. Separation of the liquid portion of the mixture by mechanical means. A concentrated salt solution is obtained which is worked up for the recovery of potash, and a saccharate which is repeatedly washed with water, the washings serving to dilute the molasses.
5. Saturation of the saccharate with carbon dioxide.
6. Separation of the sugar solution from the mud.
7. Removal of the lead from the sugar solution, with subsequent filtration if necessary.
8. Evaporation of the sugar solution.
9. Regeneration of lead oxide, and carbon dioxide from the washed saturation mud.—J. L. B.

Beetroot Sugar, Possibility of Presence of Lead in. Altschul, Pharm. Central, H.N.F. 1895, 16, 707.

IN view of Kassner's process for the recovery of sugar from molasses, &c., by lead oxide (this Journal, 1895, 978; also preceding abstract) the author discusses the possibility of beetroot sugar containing lead. According to Kassner

the principal amount of the lead is separated by treatment with carbon dioxide, but a small quantity passes over into the sugar solution, depending on the content of invert sugar and other secondary products. This should be removed by the addition of sulphurous acid or calcium sulphite. Proof will have to be given that *firstly*, traces of lead saccharate can be detected in commercial sugar by the usual qualitative methods, and *secondly*, that the separation of the lead from the sugar solution succeeds on a manufacturing scale.—J. L. B.

Dextrose, Process for Manufacturing Pure. A. L. Tedesco, Paris. Eng. Pat. 21,311, Nov. 11, 1895.

COMPRESSED air is forced into solutions prepared in the usual way for saccharification or crystallisation, by means of jets or perforated pipes. The jets penetrate the liquid in as many directions as possible, so that the dynamic impulsion which characterises the invention may be fully exercised. The pressure of air varies according to the quantity and quality of the solution, and of the acids, diastase, &c. employed. Partially converted material after being slightly acidulated, may be treated in a similar manner.—J. L. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Enzymes of some Yeasts. E. Fischer and P. Lindner. Ber. 1895, 28, 2034—2039.

In the first part of this paper there is an account of the author's experiments on the behaviour of melibiose towards top and bottom fermentation yeasts (this Journal, 1895, 1056). *Behaviour of Monilia Candida towards Cane Sugar and Maltose.* C. E. Hansen has made the observation that *Monilia Candida* ferments cane sugar, but contains no invertase. In their first experiments the authors were able to confirm this statement. Subsequently, however, they found that if the dried yeast be allowed to act on a cane-sugar solution for 40 hours at 33°, and in the presence of anaesthetics, 40 to 60 per cent. of invert sugar is obtained. It thus appears that the dried *monilia* contains an enzyme insoluble in water which can invert cane sugar. If kept for a long period in the presence of toluene it becomes inactive. It was observed that when the fresh yeast was triturated with powdered glass, and allowed to act on a solution of cane sugar for 16 hours at 33°, 7 per cent. of the sugar was inverted, an amount not augmented by continuing the action for 24 hours. From these observations the authors conclude that in the action of *monilia* on cane sugar, inversion precedes fermentation. The inverting enzyme appears to be a body insoluble in water, and is probably a constituent of the living protoplasm. Maltose is fermented by the fresh and dried yeast, and by an aqueous extract of the latter.

It is known that *Saccharomyces Apiculatus* does not ferment cane sugar, and the authors have failed to find any inverting enzyme either in the fresh or dried yeast.

—J. L. B.

Mixed High-fermentation Yeast, Researches on the Composition of. H. van Laer. Bull. de l'Ac. soc. Belge des Chimistes, 9 (7), 216—222.

THE yeast forming the subject of the investigation was one of mixed race that had been constantly employed, with regular results, for three years in one brewery. For the analysis of its constituent races, Lindner's small drop culture method was employed, the colonies being then cultivated on plates and subsequently in flasks. The system of classification adopted was to consider as *predominant yeasts* those forming the largest number of compact aggregations. Such were found to be—

1. *Sacch. cerevisia A.*—A yeast which, in wort cultures, consists of large round cells, slightly oval in form and united into clusters, but becoming decidedly oval on cultivation in sterilised Froberg beer. The gelatinised wort plate colonies resemble white eupolas, but the giant colonies are disc shaped with raised edges. In attenuation this yeast belongs to the Froberg-Logos class, quickly fermenting dextrose, levulose, maltose, and the carbohydrates degraded by Froberg yeast, and also attacking saccharose when inverted by its sucrase.

2. *Torula A.*—In wort cultures the cells are very small and ellipsoidal, collecting in flakes which imprison other yeasts when present. The plate (gelatinised wort) colonies are columnar, and the giant colonies form smooth whitish discs. This yeast attacks dextrose and levulose, and first inverts and then degrades saccharose, but is inert towards diastatic starch-transformation products and only ferments beer wort to a slight extent, although reproducing itself abundantly therein. It imparts an agreeable flavour and odour to the liquid it ferments, but its chief characteristic is its power of clarification by enveloping and carrying down the other yeasts, a faculty clearly exemplified by the parallel experiments made on this point.

The minority yeasts consisted of two forms of *Sacch. Pastorianus*, designated A and B, the first-named being of Froberg-Logos type, but less energetic than *S. cerevisia A.*, which it resembles in its action on sugars. In wort it forms large, solitary, elliptical cells, becoming pastorianic when developed in Froberg beer.

The second *pastorianus* type was present in the initial yeast in quantity too minute to be detected, but occurs largely in the sediment deposited by the beer. It assumes a variety of odd shapes, especially during secondary fermentation. In plate cultures the cells are spherical and tangential to the surface of the gelatin; the giant colonies finally hollow out the gelatin by liquefaction.

Although it would at first sight appear likely that from its low fermentative power the *Torula A.* would be crowded out by the other and stronger yeasts, yet this is not the case, analysis of the mixed yeast at the end of three and six months revealing the following constitution of 20 cultures:—

Yeasts.	After Three Months.	After Six Months.
<i>S. cerevisia A.</i>	9	8
<i>Torula A.</i>	7	10
<i>S. Pastorianus A.</i>	3	2
Undetermined	1	2

This persistence of *Torula A.* is due to its high co-efficient of reproduction, which under the circumstances of the present investigation is represented by 0.272, *S. cerevisia A.*, having a value of 0.068, *S. Pastor. A.*, 0.064, and *S. Pastor. B.*, 0.067. These values are for weight of yeast produced during fermentation and depend on the conditions under which that action occurs, but if established on a numerical basis *Torula A.*, by reason of the small dimensions of its cells, would be still farther ahead of the others. These results are considered as exemplifying one of the factors influencing stability of constitution in mixed yeasts.—C. S.

Saccharomyces Pombe, The Dextrin-fermenting Yeast.
Windisch. *Woch. für Brauerei*, 12, 1895, 655—656.

THE attenuative power of this fission yeast, which was described by Lindner (*Woch. für Brau.* 10, 1298), has been investigated by Dr. Rothenbach, who compared it with yeast race II., a yeast of high attenuative power of the Froberg type. In a 14 per cent. malt-wort free from diastase, race II. fermented 10 per cent., while *Pombe* yeast fermented 12 per cent. A 24 per cent. wort was fermented down to 3.5 per cent. by race II., and to 2.2 per cent. by *Pombe* yeast. As race II. ferments the sugars completely, *Pombe* yeast must attack the dextrin. *Pombe* yeast shows particular resistance to infection by fission fungi, a fact which is explained by the comparatively large amount of acid it forms during fermentation. From this it is concluded that the more acid a yeast forms, the more inimical it is to fission fungi. *Pombe* yeast possesses a higher attenuative power than Froberg yeast or Logos yeast.—J. G. W.

Pure Yeasts, The Reducing Power of. Nastukoff.
Comptes rend. 121, 535—536.

THE author has studied the reducing power of various pure cultures of wine and beer yeasts on magnesium sulphate, using, as a means of measuring the action, the colour produced by the resulting sulphide with bismuth subnitrate. The reducing action varies but very slightly for the same yeast under similar conditions, while different races of yeast have very different reducing powers (e.g., the wine yeast of Champagne has four times the reducing action of the beer yeast of Brussels). The reducing action in no way agrees with the quantity of alcohol produced or carbonic acid gas liberated.—J. G. W.

Yeast, Novel and Singular Formation of Asci in the case of a. H. Schöning, Meddelelser, Carlsberg, Laboratoriet, 1895, 4, Part I., 30—35.

IN 1893 the author found a new species of yeast on Italian raisins. When cultivated in beer wort it produced slight fermentation, and reproduction took place by fission instead of by gemmation. Propagation by means of ascospores was also observed. The formation of asci is effected in the following very characteristic manner:—After three to six days the cells become shorter and rounder; one cell divides into two contiguous cells, which reunite in the form of an hour-glass and gradually become elliptical. A refractile protoplasm with a constant slow motion is observed; it contains large and small granules and large vacuoles. The shape of the asci are variable, but the elliptical and hour-glass forms predominate. This yeast slowly ferments maltose and dextrose, but not cane sugar.

A culture of Beyerinck's *Schizosaccharomyces octosporus* has been examined, and the author finds that asci are formed in the manner above described, and that a similar irregularity in the number of ascospores is noticeable. Since the morphological characters of the two yeasts are alike, the author concludes that they are identical.—J. L. B.

Pectase, its Occurrence and Preparation. G. Bertrand and A. Mallèvre. *Comptes rend.* 121, 726—728.

FROM numerous experiments made by the authors, pectase may be regarded as of universal occurrence among green plants, though in varying amount. It varies considerably in amount in various organs of the same plant, being most abundant in the leaves, from which it probably extends to the other organs. The authors have prepared this ferment for the first time from the leaves of lucerne and clover by a method similar to that employed in the preparation of diastase.—J. G. W.

Amylase (Diastase), some Experimental Investigations, and their Bearing on Practice considered. J. Effront.
Monit. Scient. 1895, 541—559 and 711—725.

THE following conclusions are arrived at:—

1. The amount of active diastase contained in a malt infusion depends—apart from other considerations—on the temperature of extraction. An infusion possessing the maximum activity is obtained at 40° C. At other temperatures, whether higher or lower, and no matter how long

extraction is continued, the resulting infusions are decidedly less diastatic. Extracts prepared at 15°—35° C. and 45°—55° C. respectively, have about the same strength, equal to 70—80, as compared with an infusion made at 40° C. (= 100). At 60—65° C., diastase is more restricted, and reduced to 40—60 per cent. of the maximum.

2. The time required for complete extraction depends on the temperature and on the state of sub-division of the malt. At 15° C. the diastase available at that temperature is extracted from finely powdered malt in 6—12 hours. As regards crushed or bruised malt, and using 4 parts of water for extraction, 40—50 hours of contact are required, which may be reduced to 15—17 hours by frequently stirring the mash. At 45° C. extraction is complete in 10 hours—when often stirred, in 3 hours. At 60° C. these times are reduced to 7 and 1½—3 hours respectively.

3. The saccharifying power of diastase is greatest at 55°—60° C. Its activity, however, diminishes as saccharification proceeds, in proportion to the percentage of maltose formed. At 50° C. the rate of saccharification, and, concurrently, destruction of diastase is diminished, whilst at 30° C. hydrolysis proceeds, although slowly, without loss of active material. An excess of starch (in solution) in no way retards the destruction of saccharifying diastase at a temperature of 55°—60° C. On the contrary, the diastase is weakened more rapidly than when heated alone. The conversion products (maltose, &c.), however, appear to exert a slight but unimportant protective influence.

4. Barley and malt contain certain substances which, although themselves inactive, stimulate the saccharifying of diastase. The saccharifying power of malt is, therefore, not proportionate to the amount of diastase present.

5. This accelerating influence is, however, very pronounced, only during the early stages of saccharification, and rapidly diminishes as the degree of conversion increases. In the analysis of malt, no distinction is made between active and exciting material, although under the conditions obtaining in practical brewing, &c. they behave very differently.

6. The saccharifying and liquefying functions of malt are dissimilarly affected by physical and chemical agents. Barley-extract, phosphates, and certain other substances, stimulate saccharification, but do not influence liquefaction. 0.4 per cent. of lactic acid added to malt-extract increases its saccharifying power, but decidedly hinders liquefaction. A temperature of 65°—70° C., decidedly harmful to saccharification, has no effect on the liquefying power of diastase. In the valuation of malt, both functions of diastase should be taken into account.

7. The saccharifying power should be determined in the wort prepared by mashing the malt at 60° C. The resisting power of the diastase to heat thus becomes known. It is this point which is of special importance in the case of malt intended for brewing.

8. Diastase suffers less change in fermenting worts than in such as are not fermenting.

9. The residual diastase contained in wort (distillers') after 38 hours of fermentation, is a guide as to the nature of the final result to be expected.

Methods for the determination of diastase in malt and fermenting worts are described, and some hints given as to the interpretation of results.—H. T. P.

Organic Acids, Influence of, on Alcoholic Fermentation.
F. Lafar. *Thiel's Landwirthschaftlich. Jahrbuch*, 1895, 445—474.

THE author has investigated the influence of the addition of various organic acids to unfermented must—either in its normal condition, or neutralised with calcium carbonate, or made slightly alkaline—on its fermentation by various races of wine yeasts. The various acids have differing effects upon the same race of yeast, whilst the same acid has a varying influence on different yeast races. With acetic acid the influence on the fermentation by means of different yeasts, as shown by the time-curves of carbon dioxide production, is very different, but the time-curves of alcohol production do not agree with the carbon dioxide ones, thus pointing to the conclusion that the influence is not only upon the progress of the fermentation, but also upon its chemical form.

The addition of acetic acid, as compared with that of other acids, gives by far the least yield of glycerin and also the least crop of yeast, whilst the alcohol production in no way takes the last place, from which the author concludes that acetic acid affects the vegetative life of the yeast cell without equally influencing its fermentative power.

The addition of 0.27 per cent. of acetic acid has no appreciable effect on fermentation, which was still possible with the whole of 15 races of yeast experimented with when the amount was increased to 0.78 per cent. With 0.88 per cent., fermentation was stopped in one case, and in 12 out of the 15 when the amount equalled 1 per cent.

—J. G. W.

Malting and Brewing, Amount and Nature of Acids produced in. E. Prior. Bayer. Brauer J. 1895.

In the process of brewing, so long as the temperature is low enough to permit of bacterial development, organic acids are formed, which partly combine with the lime and magnesia of the water and react on the phosphates, forming primary phosphates.

There is an increase of acidity during the boiling of the goods and hopped wort, due to the interaction of the acid phosphates and the organic acid compounds of lime and magnesia, as well as to concentration.

At certain temperatures the acidity of the wort may decrease, partly through the neutralisation of the free organic acids by the phosphates of lime and magnesia, and partly from the volatilisation of the acids.

A certain amount of acidity is imparted to the wort by the hops, but no increase of acid is noted while the wort is in the cooler.—C. S.

Alcoholic Fermentation, Role of Organic Acids in.

F. Lafar. Landwirthsch. Jahrb. 1895.

Wine Yeasts and Acetic Acid.—In carrying out the experiments described in this paper, the author made use of sterile grape must, either normal or neutralised by precipitated chalk, additions of various organic acids being made to different portions of the neutralised medium. The wine yeasts employed in the first series were of the Schazhoberg and Geisenheim races, and were found to differ considerably from each other in presence of acetic acid, the latter being the more active of the two. In both instances the presence of this acid lowered the reproductive power of the cells and lessened the production of glycerin, without having much effect on the quantitative formation of alcohol. Further experiments, however, showed that whilst Geisenheim yeast will stand over 0.74 per cent. of acetic acid in normal must, and above 1 per cent. in neutralised must, fermentation is retarded and the production of alcohol diminished when the acetic acid exceeds 0.27 per cent. Further investigation revealed the fact that of fifteen yeasts examined, all were able to stand 0.78 per cent., and all but one, 0.88 per cent. of acetic acid, but only three could resist 1 per cent. By comparing the amount of alcohol produced with the number of yeast cells gathered, it is found that the presence of acid increases the anaerobic functions of the yeast cell.—C. S.

Alcoholic Fermentation [Wine], Determination of the Heat liberated in. A. Bouffard. Comptes rend. 121, 357—360.

The high temperature produced by fermentation and the refrigeration in consequence necessary, are serious obstacles to vinification in warm countries. The determination of the quantity of heat liberated in this process is therefore important.

Employing Favre and Silbermann's thermal data, the quantity of heat set free by the fermentation of 180 grms. of sugar, is calculated as 71 calories. But taking Pasteur's figures for the proportion of sugar which suffers decomposition into glycerol, succinic acid, and carbon dioxide, and Berthelot's recently corrected heats of combustion, the calculated number becomes 32.07 cal.

As a mean of four calorimetric determinations made on must, the author obtains 23.5 cal., a number which, while approximating to the lower calculated value, is still materially less. The author concludes that, as this direct

determination shows that the quantity of heat liberated lies between 24 and 32 cal., it is unnecessary to reckon on 71 in the construction of refrigerators, &c.—E. W. W.

Gum contained in Wine. G. Nivière and A. Hubert. Comptes rend. 121, 360—362.

PASTEUR and Béchamp, and many previous investigators, have stated that the gum contained in wine is of the same kind as gum arabic. The authors find, however, that there are the following well-defined differences between the properties of the two bodies:—(1.) The gum of wine is more easily oxidised by nitric acid. (2.) On boiling with dilute sulphuric acid, gum arabic forms arabinose, the gum of wine, galactose. (3.) Reducing agents transform gum arabic into arabinite, but the gum of wine into dulcitol. The authors divide the gums contained in wine into two classes:—

(1.) The natural gum, which exists in the grape, and is found in ordinary wine. This consists for the most part of pectin, and is similar in properties to the pectin discovered by Fremy, which, like it on oxidation, gives mucic acid (not the pectin of Scheibler; this does not form mucic acid). This gum of wine may be regarded as formed from n molecules of galactose, with elimination of water, just as dextrin is made up of n molecules of glucose. Dextrin and this gum have, moreover, many properties in common, *viz.*, solubility in water, precipitation by alcohol and by the salts of the alkaline earths and metallic salts in alcoholic solution. Both have the same solvent power on phosphate of lime. Their action on polarised light is different, and the gum of wine is precipitated by chloride of iron in presence of chalk and very dilute alcohol, whilst dextrin does not give this reaction.

(2.) The gum formed by reduction of sugars in consequence of bad fermentation. Maumené calls this variety viscose. It is precipitated by lead acetate, and is present with mannite, which clearly indicates its origin from sugars, for the wine gum would form dulcitol. Desfosses finds that viscose on oxidation forms oxalic acid without mucic acid. The authors regard its constitution as made up of n molecules of levulose with loss of water.

In order to distinguish wine made from raisins, or at least to obtain another indication, the following method is given:—A polarimetric measurement of the wine is first made; the gums of the first class are then precipitated by ferric chloride, and a second measurement then follows. Certain badly fermented French and Algerian wines would, however, give precisely the same reactions.

The amount of natural gum in a wine, may be estimated by converting it into mucate of iron, calcining and weighing the oxide of iron formed.—E. W. W.

Beer-Worts, Coloration of, by Iron, during Hop-Boiling. Kukla. Wochenschr. f. Brauerei, 1895, 12, 1061—1062.

The author has carried out experiments which show that the additional coloration produced by boiling a wort with and without hops, depends respectively upon the hops themselves, and upon the concentration of the wort. The colouring produced in the wort by boiling *per se* is proportionately greater than that brought about by the influence of hops, at least, so far as the better sorts are concerned.

Worts were boiled with hops in the presence of oxide of iron, which was added in the form of chloride in quantities varying from 0.0013 to 0.0264 gm. per 100 grms. of malt. The coloration, in proportion to the iron present, was less than when the worts were boiled with hops; small amounts of iron produced cloudy worts, whilst larger quantities acted as a clarifier. The results of the examination of the spent hops indicated that the blackening of the hop heads varied according to the amount of iron that had been added. The blackening is caused by tannate of iron, which adheres to the heads, and is distributed to only a small extent in the wort. The estimation of albuminoids showed that the coloration was dependent on the amount of these that remained in solution.

A direct colouring was not caused by oxide of iron during the process of hop-boiling. The wort also loses colour in proportion to the quantity of oxide of iron present, a

circumstance evidently due to the separation of more albuminoids from the solution. The precipitated tannate of iron being insoluble in water exerts no colouring effect on the beer.

Windisch cites a case in which a brewery employed a hop extractor. The water used for brewing was rich in iron and the additional colouring was very pronounced. During fermentation, however, it disappeared, whilst the yeast was coloured bluish-black.—J. L. B.

Duration of the Mash, Influence of, upon the Extract and the Composition of the Wort. L. van Dam. Woch. für Brauerei, 12, 1895, 711.

The yield of extract depends more on the mashing temperature than on the time of standing on the goods, owing, the author states, to the existence of two kinds of starch in malt, one readily soluble at 62–64° C., and the other soluble only after previous gelatinisation at 70° C. The nearer then the mashing temperature is to 70° the greater will be the extract.

The author divides the nitrogenous constituents of wort into albumins, peptones, and amides, the first of which are useless to the fermentation, but may, under the influence of bacteria, favour diseases of the beer. Their degradation into peptones and amides by means of peptase, the most favourable temperature for which is 40° to 45° C., is therefore advisable. The author gives the results of two mashes, one made and kept at 40°–45° C. for 2 hours and then heated up to 62°, and the other heated immediately up to 70°, from which it appears that the first mash yielded a greater quantity of nitrogenous constituents but a larger proportion of peptones and amides than the second one.

According to the author, lactic acid effects a greater solubility of albumin and also increases fermentation. The development of the lactic acid bacteria is increased by standing of the mash at a temperature of 40°.—J. G. W.

Carbon Dioxide, Collection and Utilisation of, in Breweries. H. Kerr-Thomas. Jouru. Fed. Inst. Brewing, 1896, 2, 6–16.

The following is a description of the plant employed by the author for the collection of carbon dioxide from the fermentation vats, and the subsequent purification and compression of this gas.

The gas, which is collected, as soon as the beer becomes saturated, from the fermenting vessel by means of a parachute, passes through the suction main to the compressor. The latter is of the three-stage type, and has three cylinders, each of which raises the pressure by an equal amount to the point required for the liquefaction of the gas. The purification takes place after the first compression, when the gas is at a pressure of 20 lb. above that of the atmosphere. The purifying scrubbers consist of a series of cast-iron vessels, and contain water through which the gas is made to bubble. The water is frequently changed. By this treatment, the gas is freed from yeast particles and mechanical impurities; it is then led to a second series constructed of lead, and containing sulphuric acid, which brings about the elimination of odorous principles. After this, the gas is conducted through a solution of potassium permanganate and sodium carbonate in order to remove any traces of acid, and, after being dried, it passes to the second and third cylinders of the compressor. Here it is subjected to a pressure of about 700 lb. per sq. in., and is passed through a copper coil submerged in a tank of water, whence it issues as a liquid of sp. gr. 0.8, and is collected in the ordinary steel flasks.—J. L. B.

English Beer, A Viscous Bacillus in. L. Vandam. Bull. de l'Assoc. Belge. 1895, 9, 245–257.

In the course of an examination of a yeast from Burton producing ropiness in beer, the author has isolated a ferment resembling in some particulars the *Bacillus viscosus* I. and II. of van Laer, but differing in several important respects from these organisms as described by Fellowes (this Journal, 1894, 1080), its powers increasing, rather than otherwise, by successive cultures in solid media.

B. Viscosus III., as this ferment is styled by the author, occurs as short rods, varying in length between 1.3 and 2.0

μ , and about 0.7 μ in thickness, mostly as isolated cells containing a spore; less frequently in short chains, except in wort cultures, when the chains are larger, more numerous, and embedded in a viscous mass. In hopped wort cultures at 28° C. ropiness sets in after 48 hours and continues until the whole is of the consistency of white of egg, but the energy of the organism decreases with age, although its reproductive powers are unimpaired. The ferment does not cause evolution of CO₂ or any other gas, nor does it develop on gelatinised meat extract, but on the other hand, it grows freely in gelatinised wort, thus exhibiting marked contrasts to *B. viscosus* I. and II. In yeast-water it attacks glucose, maltose, and saccharose quantitatively, in the order named, but in presence of peptone the relative positions of glucose and saccharose are reversed, the effect of the ferment being at the same time greatly diminished; however, the resulting viscosity is not affected by the quantity of the nitrogenous matter.

The most favourable temperature for this bacillus is between 28° and 30° C., and it is essentially aerobic in habit, refusing to grow at all in the absence of air.

For the production of ropiness by *B. viscosus* III. it appears necessary that infection should occur before, or at any rate, not later than, the time the wort is pitched, since attempts made at inoculating fully fermented beer failed, one reason for this being that dextrin is less readily assimilable by the bacillus than maltose. The employment of infected yeast is inadvisable although the bacillus may be present merely in slight quantity, because the reproductive power of the organism is such that in the course of a few generations it will have multiplied to an extent capable of making the beer decidedly ropy. This effect depends for its intensity on the amount of the bacillus present and not on the quality or preparation of the wort, the addition of, for example, invert sugar, exerting, so far as has been observed, no influence on ropy fermentation.

In view of the fact that lactose is eliminated by *B. viscosus* III. the author suggests that this property may perhaps be employed for the detection of the organism, as also for I. and II., although the effect of yeasts, &c. on the assimilation of this sugar has yet to be studied.

—C. S.

Cellulose, Fermentation of. V. Omelianski. Comptes rend. 121, 653–655.

According to the author *Bacillus amylobacter* is only a collective species, comprising a great number of distinct butyric ferments. From the mud of the river Neva, working in the following manner, the author has isolated a bacillus, 6–7 μ long, 0.2–0.3 wide, which has a very vigorous action on cellulose:—The mud was sown in a solution of potassium phosphate and magnesium and ammonium sulphates, containing Swedish filter-paper and chalk and a small quantity of gum arabic. The bacillus collects on the filter paper and is obtained in a pure state by heating the culture up to 90° C. several times for five minutes, and making anaerobic cultures on cooked potato.

A Material Suitable for Use in Brewing and for other Purposes. An Improved Method of Manufacturing from Starch or Starchy Substances. R. C. Garton, Battersea, and C. H. Meyer, Shepton Mallet. Eng. Pat. 24,511, Dec. 17, 1894.

ONE HUNDRED parts of dry powdered starch or starchy material is introduced into a suitable machine and intimately mixed with $\frac{1}{4}$ to 4 parts by weight of acid (preferably sulphuric) of sp. gr. 1.81, diluted to sp. gr. 1.001 to 1.060. The moistened material which is still in a powdered condition is transferred to a converter, and subjected to a steam pressure equivalent to a temperature of 270° to 300° F., which is maintained until the starch is saccharified, and a sample shows little dextrin when treated with alcohol. A heavy gravity syrup is obtained, which, on being neutralised and filtered, has, without any evaporation, the same degree of concentration as is usual after the first evaporation in the ordinary process of manufacture. A syrup of greater concentration may be prepared by employing dry or superheated steam.—J. L. B.

Malting Wheat, Improved Method of. R. W. Clarke, Reading. Eng. Pat. 20,798, Nov. 4, 1895.

THIS improvement consists in cleansing the grain, steeping it for 24 hours in water made slightly alkaline with lime, running this off and adding more fresh water until the grain has absorbed 30 to 35 per cent. The grain is drained, allowed to remain in the cistern for 12 hours, spread out on the floor of the kiln, and germinated until the rootlet has attained the length of the grain. The temperature of the air beneath the kiln-floor is maintained at 90° – 95° F., and must not exceed 100° F. The inventor states that a wheat malted in the above described manner is more suitable than the ordinary malt for use in combination with unmalted wheat in the manufacture of bread, &c.—J. L. B.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY AND WATER PURIFICATION, DISINFECTANTS.

(A).—CHEMISTRY OF FOODS.

Bread, The Distribution of Nitrogenous and Mineral Matters in. Balland. Comptes rend. 121, 786–788.

THE crust of bread does not contain more nitrogenous and mineral matters than the crumb, provided they are both brought to the same degree of dehydration. The baking of bread is effected without loss of matter, for though the constituent elements of the flour are modified by a loss of fatty matters and an increase in sugars, their respective weights do not vary in an appreciable manner, and it may be laid down that desiccated bread does not contain more nutritive matter than the dry flour employed to make it. The determination of the water in a flour will thus enable us to calculate the quantity of bread, of a given degree of hydration, it will produce, and the simultaneous determination of the water in the bread and in the flour will enable us to make certain that the yield of bread has not been improperly increased by a too great addition of water.

—J. G. W.

Rice, The Composition of, Imported into France. M. Balland. Comptes rend. 121, [17], 561–564.

THE author shows by a most complete series of analytical results the composition and dietetic properties of various varieties of rice (raw, husked, and in process of preparation) that are found in the French markets. The percentage composition of husked rice varies as follows:—Water, 10.20–16.00; nitrogenous matter, 5.50–8.82; fat, 0.15–0.75; amylaceous matter, 75.60–81.35; cellulose, 0.18–0.42; ash (phosphatic) 0.11–0.58. The rice of Carolina and Cochín China contains the largest proportion of nitrogenous constituents.—E. J. R.

Extract of Meat, Composition of. J. König and A. Bömer. Zeits. Anal. Chem. 34, 1895, 548–562.

A CHEMICAL examination of extract of meat led to the following conclusions:—

1. Precipitation with 80 per cent. alcohol, as originally recommended by Liebig, can give no idea of the kind of nitrogenous substances present, or of the quality of the extract of meat.

2. In order to form an opinion of the extract it is necessary to salt out the aqueous solution with ammonium or zinc sulphate (compare following abstract). The solid salt is added to the solution, which is constantly stirred until it is thoroughly saturated and the precipitate is afterwards washed with a saturated solution of the salt. The precipitate produced by ammonium sulphate is best weighed in the usual manner and the quantity of albumoses then calculated by estimating and subtracting the ammonium sulphate in the weighed residue. The nitrogen in the zinc sulphate precipitate can be directly determined by Kjeldahl's method.

3. The filtrate from the salting-out process is tested for peptone by the biuret reaction, if necessary, after decolorising with animal charcoal. If this reaction gives negative results peptones are either not present at all or only in such quantities as may be neglected.

4. It is desirable to estimate the ammonia in extract of meat by distilling the aqueous solution with calcined magnesia.

5. If the extract of meat has been proved to be free from peptones, then the precipitate produced by phosphotungstic acid, i.e., the nitrogen of the same after subtracting the nitrogen occurring as (gelatin + albumose + ammonia) may be considered as due to meat bases. It is to be noticed that the filtrate from the phosphotungstic acid precipitate should stand for a sufficiently long time (5–7 days) in order to separate out all the bases.

6. The difference between the total nitrogen minus the nitrogen in the form of (gelatin + albumoses + meat bases + ammonia) gives a measure of the quantity of other nitrogenous compounds occurring in the extract of meat which cannot be precipitated by phosphotungstic acid.

—J. S.

Albumoses, Zinc Sulphate, a Precipitant for. A. Bömer. Zeits. Anal. Chem. 34, 1895, 562–567. (Compare preceding abstract.)

THE author proposes to use zinc sulphate instead of ammonium sulphate as a precipitant for albumoses. The advantage claimed for zinc sulphate is that the nitrogen can be directly estimated in the precipitate by Kjeldahl's method. Another advantage that accrues from the use of zinc sulphate is that the peptones, meat bases, &c. can be directly determined in the filtrate from the albumoses after acidifying with an equal volume of dilute sulphuric acid (1:4). Test experiments, so far as they have gone, show that the use of the new precipitant is highly satisfactory.—J. S.

Raising the Temperature of Organic Substances and Alimentary Products generally, and particularly for Thawing Frozen Meat, Method of and Apparatus for. A. M. Clark, London. From La Compagnie de Carnes Congeladas, Buenos Ayres, South America. Eng. Pat. 5588, March 16, 1895.

THE present system of thawing a large bulk of frozen meat occupies so long a time that the exterior portions are liable

* 4–5 c.c. of the liquid are treated with caustic soda solution, and to the mixture is added, drop by drop, a dilute (about 10 per cent.) solution of copper sulphate. The presence of peptones is manifested by the formation, in the cold, of a reddish-violet coloration.

to become unfit for sale, while the interior is still frozen. The object of this invention is to remedy this inconvenience by establishing an internal circulation of the heat within the mass, by alternate compression and rarefaction of heated air, which process also causes the destruction of organisms and prevents the escape of valuable juices. The apparatus consists of a closed chamber provided with end covers suitably held together. The meat is hung by hooks attached to roller carriages running on the suspension rail. The chamber is connected with pipes for the introduction and withdrawal of high-pressure air, controlled by stop-valves and connected with vacuum pumps or with compressors. The desired temperature within the chamber is attained by means of a series of hot-water pipes.—L. de K.

Milk and other Liquids, Apparatus for Sterilising. H. H. Lake, London. From P. J. Buus, Aalborg, Denmark. Eng. Pat. 11,908, June 5, 1895.

The apparatus consists of a horizontal chamber surrounded by a steam jacket, in which a shaft furnished with helical wings revolves. These give a centrifugal motion to the milk and eventually force it through the outlet to the upper part of the cylinder. The steam enters the jacket near the exit tube, so that the milk is most heated on leaving the chamber.

The air-space in the middle of the chamber is kept at atmospheric pressure by being connected with the outer air by a tube.—L. de K.

An Improved Food for Animals, and Process for Manufacturing the Same. F. V. Friderichsen, Copenhagen, Denmark. Eng. Pat. 13,176, July 8, 1895.

Blood is treated so as to render it suitable as a forage by mixing 700 parts of blood with 400 parts of molasses, and the mass is then absorbed in a mixture of, for example, 500 parts of bran and 500 parts of palm-meal. The compound is subsequently kneaded, pressed, dried, and finally made into cakes or coarse powder.—L. de K.

Sterilising or Pasteurising Milk and other Liquids, Improvements in or relating to Apparatus for. A. J. Boulton, London. From H. Davidson, Gottenburg, Sweden. Eng. Pat. 18,767, Oct. 7, 1895.

The inventor claims improvements in that the apparatus consists of three vessels, one inside the other, so arranged and fitted with sockets and tubes that the milk may pass down a central tube fitted with a strainer and upwards into the middle vessel, whilst the heating medium flows down another central tube and into the outer and inner vessels. The latter contain a large cylinder of air, which by reason of its low specific heat, requires less fluid to reach and maintain the requisite temperature. The inner and middle vessels may be easily removed from the outer ones.—L. de K.

Fats for Use as a Comestible, Improvements in Preparing. David Gray, jun., Inverness. Eng. Pat. 21,103, Nov. 7, 1895.

This specification describes the production of peptonised fat, which, while having special digestive properties, will serve as a substitute for butter. Refined sweet beef fat, rendered at a temperature not exceeding 130° F., is introduced into enamelled jacket boilers, in which has been standing for 96 hours, a mixture of three parts of glycerin (to act as a solvent), five parts of water, and eight parts of digestive mucus from the upper stomach of sheep or pigs. The proportions used are 112 lb. of fat to 4 lb. of this mixture. The contents of the boilers are heated for two hours, at 100° F., and mechanically stirred. After this, the peptonised fat is filtered and left in enamelled vats for 30 minutes at 100° F. Then for every 112 lb. of fat, 12 lb. of edible cotton-seed oil and $\frac{1}{2}$ lb. of salt are added. The whole mass is stirred for 15 minutes and is then ready for packing. The inventor states that this product, which he terms "Oleotene," is devoid of fatty flavour or taste.—C. A. M.

Fish Liver, An Improved Process for the Preservation and Preparation for Transit of. C. M. V. Dahle, Stamsund, Norway. Eng. Pat. 22,887, Nov. 25, 1895.

The aim is to preserve fish liver without using an antiseptic such as boracic or salicylic acid, as it has been proved that these substances are unwholesome.

The liver is first dressed with sterilised water to remove all clots, fibres, &c., and it is then dried in air at about 30°–40° C. After soaking in a sterilised 10 per cent. solution of common salt, the liver is wiped and thoroughly boiled in oil under atmospheric pressure. This treatment causes, however, the partial destruction of the tissues and the product must, therefore, be crushed before being packed.

—L. de K.

(B.)—SANITARY CHEMISTRY.

Acetylene, The Poisonous Properties of. N. Gréchant. Comptes rend. 121, [17], 561–565.

A series of experiments on dogs shows that acetylene is poisonous when breathed in an atmosphere containing from 40 to 79 per cent. The effect of a mixture of coal gas, oxygen, and air is comparatively far more violent and is mainly due to the presence of carbon monoxide.

M. Berthelot remarked that in his own experiments the mixture he had used of pure acetylene and air had little effect on birds. M. Gréchant's results, indicated no doubt the difficulty with which acetylene forms a compound with the hæmoglobin of the blood. M. Moissan stated that pure acetylene had an agreeable ethereal odour and caused no inconvenience when inhaled in small quantities.—E. J. R.

Acetylene, The Toxicity of. L. Brociner. Comptes rend. 121, 773–774.

The blood dissolves four-fifths of its volume of acetylene, with the formation, however, of a very unstable, if any, compound with the hæmoglobin, differing greatly in this respect from carbon monoxide. Acetylene exerts a very feeble toxic action, which is not more marked than that of other hydrocarbons, such as ethylene and propylene. Animals can exist for several hours in air containing considerable quantities of acetylene, provided care be taken to remove the products of respiration.—J. G. W.

Organic Matter, Estimation of, in Water by Potassium Permanganate. V. Skupevsky. J. Russ. Chem. Soc. 27, 500.

See under XXIII., page 140.

PATENTS.

Purification of Sewage and Impure Waters, Improvements in, and in Apparatus for Use in or in connection with. F. P. Candy, Eccles, Lancaster. Eng. Pat. 166, Jan. 2, 1895.

The improvements consist in—

(1.) Causing the precipitate to aggregate previous to subsidence, by passing the sewage through a bed of pebbles on its way to the settling tank, or by passing the sewage upwardly through a chamber at such a speed that the suspended particles agglomerate, or by an improved arrangement and construction of the settling-tanks themselves.

(2.) Impregnating sewage with air or other gas by causing it to flow down a pipe, carrying bubbles of air or gas along with it; also utilising the admission of water to, and its discharge from, a closed chamber in order to pump air into a filter-bed.

(3.) Construcing upward-flow filter-beds in such a way that the dirty or fouled filtering material can be removed from the bottom and allow the cleaner upper portion to sink down and take its place, without putting the filter entirely out of use.

(4.) Improvements in the construction of precipitation-tanks, relating chiefly to the form of the bottoms of circular tanks and the means for admitting sewage and removing sludge.

(5.) An arrangement for drawing off sludge from a tank, without the orifice of the outlet-pipe becoming choked.

—L. A.

Tanks for the Precipitation of Sewage and Foul Waters, Improvements in and relating to. G. H. Skelsey, Liverpool. Eng. Pat. 2449, Feb. 4, 1895.

A precipitation tank is constructed with a series of transverse walls in such a way that the sewage flows alternately under one wall and over the next. Each division of the tank between two over-shot walls is shaped in section like an inverted bottle, and the undershot wall extends down the middle as far as the shoulder. The sludge settles into the bottle neck, whence it is drawn off from time to time.

—L. A.

Ammonia from Sewage Effluent and other Weak Ammoniacal Liquors, Improvements in the Recovery of. T. Twyman, Egham, and P. E. Matthews, Englefield Green, Surrey. Eng. Pat. 2625, Feb. 6, 1895.

See under VII., page 114.

Softening and Purifying Water, Improvements in Apparatus for. H. T. Wright, Westminster. Eng. Pat. 3366, Feb. 15, 1895.

This invention relates to apparatus by means of which water under pressure may be softened and purified without the employment of any pumping or pressure,—employing means other than may be necessary for the ordinary town or other supply. The water to be treated, enters a receiver having two outlets, a larger one, furnished with a back pressure valve, leading directly to a tower, in which the water is to be treated, and a smaller one leading first to a chamber in which the solution of the reagent employed is made. This solution is then pumped into the tube leading the main body of water to be treated to the lower part of the tower. This tower is provided internally with a vertical series of inclined surfaces, each alternate surface leaving a space between its upper part and the sides of the tower or vessel, and terminating at its lower end in a short, central pipe, and each other alternate inclined surface joining the sides at their upper part, and leaving a central opening and a space between themselves and the first-named inclined surfaces, so that the water and the treating solution pass slowly upwards through the apparatus, alternately upwards and outwards, and downwards and inwards, whilst the deposited matter falls through the central short tubes and openings to the bottom. The water may pass through more than one such tower, and then be led to a filter.

—R. S.

Purifying the Water of Hat-Felting or Sizing Tanks, Improvements in Means for. G. Wells, C. Swartz, and W. B. Hubbell, all of South Norwalk, Connecticut, U.S.A. Eng. Pat. 19,369, Oct. 15, 1895.

In order to remove hairs, particles of fur, &c. from the tanks, a pipe leads from below the level of the water to the bottom, where it is bent, and again rises. Its outlet is above the surface, and leads into a strainer, through which the water is delivered back into the tank, and constant circulation and straining thus take place. The water, of course, finds its own level in the pipe, and is forced upwards to the strainer by means of high-pressure steam introduced through a nozzle in the lower part of the pipe.—R. B. B.

(C).—DISINFECTANTS.

PATENTS.

Antiseptic, Disinfectant, and Deodorant, Improved Compound forming an. S. A. Vasey, Loughton, Essex. Eng. Pat. 788, Jan. 12, 1895.

BICARBONATE of soda is impregnated with oil of eucalyptus in the proportion of 1 pint of the oil to 1 cwt. of the bicarbonate, or other suitable proportions. 57 parts of the product are then mixed with 43 parts of bleaching powder, though these proportions also may be varied. The object is the production of a powder which, on being treated with water, yields free hypochlorous acid, thus:—

The eucalyptus oil is to preserve the powder when in a dry state. Instead of the bicarbonate, normal sodium carbonate may be used mixed with an equivalent proportion of a crystallised acid, such as tartaric, or an acid salt.—L. A.

Improvements in Sterilising and Purifying Liquids. P. Boisserand, Paris. Eng. Pat. 4514, Mar. 2, 1895.

THE patentee claims the use of the permanganates of lime, potash, or the like, in conjunction with the higher oxides of manganese (Weldon mud), for sterilising and purifying river or drainage water.—L. A.

XIX.—PAPER, PASTEBOARD, Etc.

PATENTS.

Nitrocellulose or Pyroxyline Compounds, Improvements in and Connected with the Manufacture of. F. Greening, Stoke Newington. Eng. Pat. 22,019, Nov. 14, 1894.

See under XIII., C., page 124.

Paper or Pulp, A New Product obtained from, applicable for Use as a Filtering Material, and in the Manufacture of Celluloid, Collodion, and Explosives, and for other Purposes. A. Grandjean, Paris. Eng. Pat. 22,556, Nov. 21, 1894.

This new product is produced by disintegrating paper pulp, which product the inventor terms "snow paper" or "snow pulp."

It is specially suitable for filtering purposes, or for the manufacture of cellulose, &c.—S. P. E.

Machine-Paper, with Coloured Longitudinal Stripes, Process for the Manufacturing of. A. Cohn, Prussia. Eng. Pat. 1978, Jan. 15, 1895.

This process consists of allowing several differently coloured stuffs to run upon the wet end of the machine, the differently coloured stuffs being kept separate by means of very thin plates, suitably fixed, and resting upon the wire.

This method may also be adopted for paper having longitudinal stripes upon a common ground. The coloured stuffs are run on to the ground stuff when the latter has sufficient moisture left to felt with them, and thus form a completely felted paper, having longitudinal stripes over a common ground.—S. P. E.

Wrapping Paper, Improvements in. J. C. Kaye, Wakefield. Eng. Pat. 1768, Jan. 25, 1895.

PARCHMENT paper and wrapping paper are pasted together, passed through rollers, and cut into sheets of any required size. By this means a sheet is produced, having the qualities of each paper on its respective outer surfaces, with the combined strength of both papers, for the purpose of wrapping oleaginous or moist articles.—S. P. E.

Vegetable Parchment, Improvements in Treating to make it Applicable as an Electric Insulating Material, and for other Purposes. J. A. London and H. P. Bailey, Newcastle-on-Tyne. Eng. Pat. 12,711, July 2, 1895.

A BLOTTER paper is first made from ordinary materials and run on reels in the ordinary manner. This paper is passed through a trough of sulphuric acid, kept as cold as possible. Immediately on passing from this trough it is washed with water, and re-wound on another reel. This washing and rewinding is repeated four times to make the paper more skin-like, and water and grease-proof. Weak soda may be used for washing, neutralising any free acid. The sheet is then passed through a bath of glycerin to make it pliable and to prevent curling. After drying, it is cut to the required size and sheeted in the usual way. Such parchment may be used for insulating electric conductors, for the manufacture of waterproof clothing, and many other purposes where rubber is now employed.

—S. P. E.

Supporting and Moving a Web of Paper or other Flexible Material for Coating, Drying, or other Purposes, Improved Means for. G. J. Burns, United States. Eng. Pat. 16,498, Sept. 3, 1895.

This invention relates to the coating of paper with mineral colours, and drying the same without allowing it to touch any solid support until dry.

The paper is taken from a reel, and passed between ordinary distributing brushes, the first pair of which dip into the colouring matter, coating each side of the paper simultaneously. The paper is kept at the required tension by a blast of air striking equally across the whole width of the paper, forming the paper into a loop, while another blast is forced against the under side, the two serving the purpose of a roller, without affecting or in any way marking the surface. The air also helps to dry the coloured surface, and may be heated for this purpose.—S. P. E.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Alcoholates. H. Lescœur. Comptes rend. 1895, 121, 691—692.

To set at rest the question of the proportion of alcohol of crystallisation in the solid products of the action of sodium and of sodium hydroxide respectively upon alcohol, the author has studied the manner in which these substances dissociate. He quotes the vapour tensions observed on concentrating solutions *in vacuo* at 60° C., and obtains indications of the existence of $\text{NaO} \cdot \text{C}_2\text{H}_5 \cdot 2\text{C}_2\text{H}_5(\text{OH})$ in the former, and $\text{NaOH} \cdot \text{C}_2\text{H}_5(\text{OH})$ in the latter case.

By boiling sodium hydroxide in alcohol, and then cooling, small scales are produced, which alter rapidly in moist air, dissolve in water with a rapid circular motion, fuse easily, evolve alcohol on heating, and appear to have the formula $\text{NaOH} \cdot 3\text{C}_2\text{H}_5(\text{OH})$. These last are the true alkaline alcoholates, and should be distinguished from the ethylates, such as that first described, which is an alcoholate of sodium ethylate, and yields sodium ethylate in dry air.

—W. G. M.

Methyl Nitrate, Preparation of. Delépine. Bull. Soc. Chim. 13, (1895), 1044—1045.

According to the method proposed, 100 c.c. of concentrated sulphuric acid and 150 c.c. of pure nitric acid (35°) are mixed and cooled to about 12° C. A second mixture is then prepared by carefully adding 50 c.c. of sulphuric acid to 150 c.c. of 98—99 per cent. methyl alcohol, with constant agitation, and keeping the mixture cool so that the final temperature is below 12°—14° C. The solution so obtained is then gradually added to the nitro-sulphuric acid, the temperature being kept below 15° C. When the two solutions have been thoroughly mixed, 100 c.c. of sulphuric acid is quickly added and the whole is stirred rapidly, when the temperature rises to about 20° C., and after a few minutes the ether floats up. After separating, it is washed with dilute alkali, dried, and rectified, when almost the whole passes over at 66° C. The yield from 150 c.c. of alcohol is 86 c.c. of crude ether, whilst a litre of alcohol divided into four charges gave 560 c.c., and it does not appear to be advisable to work with larger quantities.—T. A. L.

Methyleugenol, Synthesis of. Constitution of Eugenol. C. Moureu. Comptes rend. 121, 721—723.

By fixing the radical allyl on to the dimethyl ether of pyrocatechol, veratrol, the author has at once synthesised the methyl ether of eugenol, methyleugenol, and proved eugenol to be an allyl guaiacol of the constitution—

This he has effected by acting on veratrol with allyl iodide in the presence of zinc dust, whereby hydriodic acid is eliminated. This, however, as soon as liberated, demethylates part of the veratrol, producing iodides of methyl,

guaiacol, and pyrocatechol, from which substances the methyleugenol is purified by distillation, which removes the methyl iodide, and then by rendering alkaline with soda and distilling with a current of steam, which carries over the methyleugenol containing only any excess of veratrol, from which it is purified by fractional distillation. The body so obtained agrees in all its properties with methyleugenol formed from natural eugenol. The author intends to apply this method to the synthesis of other natural products possessing a non-saturated lateral chain, such as safrol, anethol, and estragol.—J. G. W.

Phenol, Action of, upon Mercurous Iodide. M. François. Comptes rend. 121, 768—770.

At its boiling point phenol acts upon mercurous iodide, decomposing it into mercury and mercuric iodide, the latter of which enters into solution. This action ceases, however when the amount of mercuric iodide dissolved by the phenol equals 2.75 grms. per 100 grms. of liquid. This evidently corresponds to a state of equilibrium, for the reverse action takes place when a boiling solution of mercuric iodide in phenol, of greater strength than the above, is brought into contact with metallic mercury. The mercury is converted into mercurous iodide, the action, however, ceasing when the content of the solution in mercuric iodide falls to the above amount.—J. G. W.

Denatured Alcohol, Production and Analysis of. Petit. Monit. Scient. 1895, 702—708.

THE regulations affecting the production (in France) of denatured spirit, require that not only the finished article, but all the materials used (alcohol, methylated spirit, &c.) shall conform in composition to particular standards; and certain methods of analysis are officially recognised. These the author has examined, and criticises in detail. He concludes that—

1. The standards for alcohol and wood spirit are, as such, meaningless, because the analytical processes adopted are insufficient to define them.

2. The denaturing processes fail to prevent fraud.

3. The methods of analysis are in some cases absolutely worthless, whilst others have been hastily adopted and very imperfectly studied.

These strictures apply especially to the methods for the determination of acetone, saponifiable ethers, and total impurities.—H. T. P.

XXII.—EXPLOSIVES, MATCHES, Etc.

Matches with Explosive Pastes. T. Schloesing. Comptes rend. 121, 331—336.

Nor only have the Académie de Médecine, the Conseil d'hygiène de la Seine, and all authorities on hygiene, condemned the use of white phosphorus in the manufacture of matches, but the workmen in the factories of Pantin and d'Aubervilliers have also demanded its suppression. In the hope of finding some substitute for this substance, the French Minister of Finance appealed to all match makers and inventors, and appointed a commission to judge of the products submitted to competition.

Some of the matches submitted to the commission fulfilled the condition of Swedish safety matches, though in a less degree, but all were made of explosive pastes composed essentially of potassium chlorate and combustible bodies, such as red phosphorus, certain sulphides, hyposulphites, &c. In fact, their composition was similar to that in common use 50 years ago, except for the advantageous introduction of red phosphorus. Though their storage and transport presents no special danger, and the paste may be prepared in large quantity if due precautions are taken, these matches—unlike the ordinary ones containing white phosphorus, which require an atmosphere containing oxygen to enable them to burn—have in themselves all the elements necessary to combustion. This is a serious disadvantage, considering

that the slightest amount of friction, such as that caused even by the rubbing of one head against another, is usually sufficient to cause ignition.

This difficulty, however, does not seem insurmountable. The author has attempted to obtain by experiment some scientific knowledge of the composition of a suitable paste. In the first place, mixtures of each of the substances which act as supporters of combustion with each of the combustible bodies in common use, were made. Glue and sand or broken glass were added, and matches were then made from the pastes. Potassium chlorate and red phosphorus proved to be the best materials, though their mixture when dry is a dangerous explosive even when combined with glue and a large proportion of an inactive substance. With sulphur, the sulphides of antimony or tin, or hyposulphite of lead, potassium chlorate forms pastes which may be ignited on a rough surface, such as slate, but not upon cloth, and these mixtures on burning tend to fuse, and not to detonate like those containing red phosphorus. With sugar, gum, or gelatin ignition is effected with greater difficulty. The other oxygenous substances—the nitrates, "oxidised minium" (a mixture of nitrate and peroxide of lead, obtained by heating red lead with nitric acid and drying), peroxide of lead, manganese dioxide, bichromates, and neutral chromates—do not give pastes which can be ignited on a match by friction, even on a surface containing red phosphorus.

From these experiments it is evident that potassium chlorate and red phosphorus must be regarded as indispensable ingredients. The effect of the addition of another combustible material to this mixture was next tried. Glue and powdered glass were employed as before. It was found that the combustion of a mixture of chlorate and phosphorus is very much moderated by the presence of a fusible body such as sulphur, the sulphides of antimony, or hyposulphite of lead. In fact, without destroying the sensibility due to the phosphorus, pastes which burn less violently and do not eject sparks, may be obtained by this means. The state of division of the materials has a great influence on their manner of combustion. If the phosphorus be in coarse powder the mixture fuses on burning, but if in a very fine state of division it detonates and emits sparks. In most cases a mixture of chlorate, phosphorus, and another combustible still ignites too violently, but this may be moderated by the addition of inert substances such as zinc oxide, insoluble chromates, or the oxides of manganese or iron.

The best idea of the composition of a suitable paste may be obtained by regarding it as a mixture of four kinds of material:—

- (1.) A supporter of combustion—potassium chlorate.
- (2.) Two mineral combustibles, of which one is invariably red phosphorus.
- (3.) Inert substances such as silica or powdered glass.
- (4.) A colloid in solution; e.g., gum or glue.

From laboratory experiments the author finds that a paste which will ignite on cloth must contain 12 to 15 per cent. of red phosphorus, and the potassium chlorate should not exceed 35 per cent., or the combustion becomes too violent. These numbers, however, would probably require modification in commercial practice.

The problem of finding the proper combustible to use with the phosphorus, the most suitable inert material, and their best proportions, concerns the manufacturer principally, and might easily be ascertained by experiment on the principles laid down.

The composition of the fumes produced on burning was next investigated. For this purpose 100 matches were burnt in a closed vessel, the fumes allowed to settle, rinsed out with water, and the liquid analysed. Six kinds of matches were used, with the results shown in table in next column.

The phosphorus is present in the fumes as phosphoric acid, the lead as white oxide, the antimony equally as oxide or antimonie acid. These figures show the necessity of avoiding accidental ignition and practically condemn the use of antimony or lead. But phosphorus cannot be avoided, though the presence of phosphoric acid in the fumes largely deprives red phosphorus of its superiority to white. Thus, the substitution of explosive pastes for yellow phosphorus becomes one of great difficulty.

PATENTS.

Nitrocellulose, and Compounds thereof, Improvements in Manufacture of. A. Luck, Bexley, and A. H. Durnford, Dartford, Kent. Eng. Pat. 4769, March 6, 1895.

In order to obviate the necessity for gelatinising gun-cotton, the inventors prepare it in one process in a dense, powdery form, so that it can be finished, like ordinary black powder, by rolling or granulating. The original cellulose is dissolved in dilute sulphuric acid, aqueous zinc chloride, zinc chloride and hydrochloric acid, or a mixture of caustic alkali, carbon bisulphide, and water. The solution is agitated, and, by dilution or heating, the cellulose is reprecipitated in gelatinous granules. These are washed and dried with constant agitation, then run through a hopper into the mixed acids, and nitrated as usual.—F. H. L.

Gunpowder, An Improved. E. Dickson, Oak Lake, Manitoba, Canada. Eng. Pat. 19,667, Oct. 19, 1895.

This powder consists of barium nitrate, 40 per cent.; wheat flour, $6\frac{1}{2}$; potassium ferrocyanide, $6\frac{1}{2}$; picric acid, 32; potassium chlorate, $6\frac{1}{2}$; liquid ammonia, 8; and lamp-black, 1 per cent. The ingredients are mixed, granulated, and treated with petroleum in a revolving drum, the spirit having been previously refined by washing with nitric and sulphuric acids and ammonia in succession.—F. H. L.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC CHEMISTRY.—QUALITATIVE.

Arsenic in Presence of Organic Matter, Detection of. Izhevsky and Nikitine. Jour. Russ. Chem. Soc. 27, 254.

The authors find that when organic matter containing arsenic is oxidised by strong sulphuric acid and potassium permanganate, as in Kjeldahl's method of nitrogen estimation, the arsenic is in general not volatilised. The clear residual liquid may be transferred at once to a Marsh apparatus and tested as usual.—J. W.

INORGANIC CHEMISTRY.—QUANTITATIVE.

Lead, Colorimetric Analysis of. M. Lucas. Bull. Soc. Chim. 15, 1896, 39—42.

The method, which may be applied to the determination of minute quantities of lead in copper, brass, waters, &c., in proportions varying between 1 and 20 mgrms. per litre, is based upon the coloration of the slightly alkaline solution caused by the addition of ammonium sulphide. The tendency of the lead sulphide to segregate, which militates against the success of the process, is greatest in those solutions which contain most lead, alkali, or soluble salt,

and is noticeable in dilute solutions in the changed colour of the liquid, even after a quarter of an hour. The colour of the solution also varies under varying conditions; in the presence of alkalis it is brownish, whilst with neutral salts it becomes greyer, and even more grey when carbonates or bicarbonates are present; and the colour density increases with the proportion of these substances. Hence the addition of salts or alkalis is to be avoided, except in very dilute solutions; and in all cases the conditions obtaining in the two liquids to be compared must be as nearly as possible identical.

In the analysis of bronze, by way of example, 1 gm. of the metal is dissolved in nitric acid, filtered to separate tin and antimony, and evaporated to 7 or 8 c.c. after the addition of 1 c.c. of sulphuric acid. After dilution, the liquid is electrolysed for 12 hours, in Riche's apparatus, with the aid of a current of 2 volts and 0.3 ampères; when the precipitation of copper is complete, the liquid is siphoned off and the deposits washed without breaking the electric circuit. The peroxide of lead on the anode is dried and weighed, to ascertain approximately the percentage of lead, which is found by multiplying the weight obtained by 0.865. Meanwhile, solutions of lead nitrate (1 gm. per litre), caustic soda (300 grms. per litre), and sodium nitrate (610 grms. per litre) are prepared, the last two being in equimolecular proportions. The deposit of lead peroxide is dissolved in 1 c.c. of nitric acid containing nitrous acid formed electrolytically from nitric acid; the crucible is washed with boiling water, and the solution and washings are neutralised by standard soda solution, added from a burette, and made up to as many times 50 c.c. in bulk as there were milligrammes of lead found by weighment, 5 drops of ammonium sulphide are then added, and the solution is well mixed. The standard for comparison is mixed with a volume of the sodium nitrate solution equal to that of the caustic soda added to the sample under examination, and the liquid is then made up to the same bulk as the sample, and mixed with 5 drops of ammonium sulphide and shaken. The colours are compared with equal volumes of liquid and in similar glasses. In very dilute solutions, the liquid should be divided into two parts, an approximate determination being made with one portion first, the second portion being then compared with several solutions containing slightly different proportions of lead, varying on either side of the number first found. The sulphide should be added to the second half and the standards simultaneously. Concordant results are obtained.—W. G. M.

Lead, Estimation of, by Electrolysis. A. Kreichgauer.
Zeits. Anorg. Chem. 9, 89.

With a current of 0.1 ampère and 9 to 13 per cent. by volume of nitric acid, a compact precipitate of lead, the author says, is obtained, provided that the vessel in which the electrolysis is carried out is placed on an asbestos card and heated from 50° to 60° over a micro-burner.

For the examination of galena, 0.5 gm. of the sample, broken into small pieces, is spread over the bottom of a large beaker glass (400—500 c.c.). Sufficient concentrated hydrochloric acid is added to cover the galena, and the whole warmed on the water-bath or asbestos card. When the reaction ceases, more acid is added until all the sulphide is converted into chloride. In the event of the ore not containing slaty matter, the end of the reaction can be determined by the disappearance of black particles. On the cessation of the evolution of hydrogen sulphide, the contents of the flask are raised to a higher temperature until the lead chloride is completely dissolved. A solution consisting of 1 part of pure potassium hydroxide and 3 parts of water is then added until the lead is again dissolved. If antimony be present, 1—2 gm. of tartaric acid is added, and the mixture warmed for some minutes from 70° to 100°. A current of carbon dioxide is next led into the cooled alkaline solution for 1½ to 2 hours. (A large excess of alkali is neutralised with hydrochloric acid before the introduction of carbon dioxide.) The precipitate is allowed to settle for a few minutes, filtered, and washed with hot water until free from chlorides. The solution of the precipitate with nitric acid (1 part nitric acid of sp. gr. 1.4 and 7 parts water) is carried out on the filter under cover of a watch-

glass, the filter being afterwards washed with acid of the same strength. The solution of lead nitrate contained in a platinum basin is electrolysed over night at the ordinary temperature, or at 50°—60° during the day.—J. L. B.

Arsenic, Gravimetric Estimation of. C. Friedheim and P. Michaelis. Zeit. Anal. Chem. 34, 1895, 505—515.

In this paper the authors discuss the methods and the errors involved in the gravimetric estimation of arsenic.

Part I. deals with the precipitation and estimation of arsenic by means of magnesia mixture, and a large number of test experiments show that the method is satisfactory. The authors, however, recommend the use of the Gooch crucible and the magnesio pyroarsenate must not be ignited for more than ¼—½ hour in a current of oxygen over a sixplex Bunsen burner (Sechsbrenner), otherwise some of the arsenic will be lost. Attempts to obviate the necessity of drying the precipitate of magnesium ammonium arsenate prior to transferring it to a Rose's crucible for ignition, gave unsatisfactory results on account of the hydrolytic action of the water on evaporation.

In *Part II.* the authors critically examine the methods for the estimation of arsenic as trisulphide. The precipitate invariably contains an excess of sulphur, all of which cannot be removed by extraction with carbon bisulphide. Further experiments show that in the freshly precipitated trisulphide the excess of sulphur does not exist as such but as hydrosulphide. On drying, only a portion of the hydrosulphide is decomposed into arsenic trisulphide and hydrogen sulphide, and, it is only that fraction of the hydrogen sulphide which is oxidised to sulphur by the action of the air that can be extracted by carbon bisulphide. Hence the authors criticise adversely the method recommended by Classen and Ludwig. Mohr's method was also found to be unsatisfactory on account of the formation of a skin on the surface of the liquid during evaporation.

The conversion of arsenic trisulphide or pentasulphide into arsenic acid, and the estimation of this as magnesium pyroarsenate has frequently been recommended. If arsenic sulphide be oxidised in the usual way with nitric acid, a considerable quantity of sulphuric acid is formed in the solution, and the authors find that the magnesium ammonium arsenate precipitated from such a solution, invariably contains sulphuric acid or rather basic magnesium sulphate. This, however, depends to a large extent on the concentration of the solution, and the basic magnesium sulphate may be almost entirely removed by a second precipitation.

Bäckström's method, which depends on the conversion of the arsenic sulphide into arsenic acid by oxidising with nitric acid and then directly weighing the arsenic acid is also unsatisfactory, as it is extremely difficult to maintain the temperature so that the last traces of the sulphuric acid will be driven off, whilst the arsenic acid remains undecomposed.—J. S.

Nickel Estimation [Nickel-Plating Solutions], New Volumetric Process for. E. Lecœur. Bull. Soc. Chim. 13, 1895, 1011—1013.

The process is devised specially for determining the strength of nickel-plating solutions, and depends upon the precipitation and re-solution of nickel by means of potassium cyanide in feebly ammoniacal solutions. A 10 per cent. cyanide solution (corresponding to about 22 or 23 mgms. Ni per c.c.) is used, and is standardised against nickel-ammonium sulphate. The nickel solution should be fairly concentrated, and if it contains no organic acid, sufficient ammonium tartrate should be added before rendering it alkaline to prevent the precipitation of iron and other similar metals by the ammonia. Working at the normal temperature, sufficient ammonia solution (5 per cent. NH₃) is added to render the liquid faintly alkaline; the cyanide is then run in, little by little, with constant shaking, until the further addition of one drop in excess converts the turbid liquid into a clear but yellowish solution. When the liquid contains less than 0.1 gm. of nickel per litre, it should be concentrated by evaporation. 100 c.c. of a 1 per cent. solution of nickel is a suitable quantity to employ. Organic acids in the nickel solution up to the point of saturation in the cold, have no influence upon the determi-

nation, but if they exceed this amount they hinder the precipitation of nickel, unless the solution be slightly warmed. In the presence of sufficient organic acids, 5, or even 10, per cent. of iron should exert no prejudicial influence. Ammoniacal salts and a small proportion of free ammonia (less than 25 grms. per litre) may be present; but a larger proportion of ammonia hinders the precipitation of the nickel. Copper, zinc, and cobalt are interfering metals; and, indeed, the two latter may themselves be determined by this process, which may also inversely be applied to the determination of cyanides.—W. G. M.

Aluminium and its Alloys, Analysis of. H. Moissan.
Comptes. rend. 121, 1895, 851—856.

SEVERAL methods are given for the determination of the various impurities in commercial aluminium as the processes hitherto employed are stated to give untrustworthy results. A preliminary investigation is necessary to test for copper by dissolving about 2 grms. of the aluminium in dilute hydrochloric acid and passing sulphuretted hydrogen through the gently warmed solution when after filtering, copper is detected in the residue. Considering first of all those cases in which copper is absent, a qualitative examination shows the presence of silicon, iron, carbon, nitrogen, titanium, and sulphur.

Silicon.—About 3 grms. of the metal are treated with 10 per cent. hydrochloric acid. A greyish residue remains undissolved containing silicon, iron, aluminium, and carbon. This is fused with a small quantity of sodium carbonate in a platinum crucible and after dissolving in dilute hydrochloric acid the two solutions are mixed and evaporated to dryness on the water-bath and the residue is finally heated to 125° C. when it forms a white pulverulent mass and no longer fumes with ammonia. It is then taken up with warm water containing a very small quantity of hydrochloric acid and after boiling a few minutes, the silica which remains undissolved is filtered off, dried and weighed.

Iron and Aluminium.—The above solution in hydrochloric acid, after separation of the silica, is made up to 500 c.c., and 25 c.c. corresponding to 0.15 grms. of aluminium are neutralised in the cold with ammonia, and the two oxides are precipitated by freshly prepared ammonium sulphide. The mixture is digested for an hour and the precipitate filtered off, washed until free from chloride, dried, calcined, and weighed. The washing is performed by decantation with boiling water and the calcination must be carried out carefully and at a sufficiently high temperature since the alumina obstinately retains traces of water.

Iron.—250 c.c. of the hydrochloric acid filtrate, after separating the silica, are evaporated to 100 c.c., and caustic potash, free from silica, is added, the whole mixture being kept nearly boiling for about 10 minutes. After washing five or six times by decantation with boiling water, the solution is filtered, the precipitate taken up with hydrochloric acid, and the treatment with caustic potash is repeated. A second washing and filtering are then carried out, and the iron is finally precipitated with ammonia. The precipitate is filtered off, washed, calcined, and weighed as sesquioxide of iron. From this and the weight of the two oxides together the percentage of iron and aluminium can be calculated.

Sodium.—The method for the determination of sodium depends upon the fact that aluminium nitrate is decomposed by heat, giving alumina, at a lower temperature than is the case with sodium nitrate. About 5 grms. of aluminium are dissolved in warm nitric acid diluted with an equal volume of water, and the solution, after evaporation on the water-bath, is evaporated to dryness on a sand-bath. The residue is then heated to a point below the fusing point of sodium nitrate until the evolution of nitrous acid vapours ceases. The residue is taken up with boiling water and filtered from the alumina. The collected washings, containing a trace of nitric acid, are evaporated, again taken up with water to get rid of any traces of alumina, and finally evaporated to dryness. This residue is then treated with hydrochloric acid, and, after evaporation, is heated to 300° C. The resulting sodium chloride is determined as silver chloride, and from this is calculated the corresponding weight of sodium.

Carbon.—About 2 grms. of the metal are ground up with 10—15 grms. of mercuric chloride and a little water, and, after evaporation, the mixture is heated in a porcelain boat in a current of oxygen. The carbon dioxide evolved is weighed in potash bulbs.

In the case of alloys containing up to 6 per cent. of copper, 0.5 gm. of the metal is dissolved in nitric acid free from chlorine, diluted to 50 c.c., and a current of 0.1 ampère is passed through the solution, kept at 60° C., for 6 hours, or for 24 hours in the cold. The copper which deposits after washing and drying is weighed in the metallic state. The remaining constituents of the alloy, aluminium, silicon, and iron, are determined in the solution freed from copper, by means of sulphuretted hydrogen.

A certain sample of aluminium gave the following results on analysis:—Al = 98.82, Fe = 0.27, Si = 0.15, Cu = 0.35, Na = 0.10, C = 0.41, N = traces, Ti = traces, S = none. For comparison, the analysis of an earlier sample, obtained from another source, is given:—Al = 96.12, Fe = 1.08, Si = 1.94, C = 0.30. If an aluminium could be obtained free from sodium and containing smaller quantities of carbon, its preservation would be a simpler matter. Besides the analysis, the physical properties, elongation, limit of elasticity, and breaking strain of aluminium must also be taken into account.—T. A. L.

Hypochlorous Acid, Action of, on Potassium Iodide.
M. E. Klimenko and B. Klimenko. J. Russ. Chem. Soc. 27, 249—253.

When hypochlorous acid acts on excess of potassium iodide in aqueous solution, one atom of iodine is liberated by each molecule of hypochlorous acid. If hydrochloric acid is present in the solution, twice that amount of iodine is set free. The authors express the actions by means of the following equations:—

—J. W.

Boric Acid, the Methyl Alcohol Process of Separation Simplified. H. Jay and Dupasquier. Monit. Scient. 1895, 709—710.

THE substance under examination, finely powdered and free from organic matter, is acidified with hydrochloric or sulphuric acid and introduced with 25—30 c.c. of methyl alcohol into a small flask provided with a stopper and two tubes. One tube dips below the surface of the liquid and is connected above to an inverted condenser; the other passes to the bottom of a second flask, which is charged with 1—3 c.c. of normal potash, and also connected by an exit tube to the condenser. Both flasks are heated by means of a water-bath. The alcoholic vapour distils directly into the receiver, where the boric acid carried over is fixed by the potash, then passes to the condenser, and from thence back to the retort, &c., &c., in a continuous manner. About 1½ hours are required to volatilise 0.3 gm. of boric acid.

The liquid from the receiver is heated to expel methyl alcohol, slightly acidified with hydrochloric acid, boiled to expel traces of carbonic acid, and *exactly* neutralised with N potash (free from CO₂), using litmus paper as indicator.

Two drops of an aqueous solution (1 per cent.) of "blue C.L.B." are now added and titration continued until the colour "turns." The additional volume of alkali required corresponds to the boric acid present. In presence of fluorides the results come out a trifle high, but still sufficiently accurate. To ensure success, titration must be conducted always under as nearly as possible identical conditions of temperature and volume, and CO₂ and methyl alcohol must be completely absent.—H. T. P.

Mercurous Iodide, Action of Alcohol on. M. François.
Comptes rend. 121, 1895, 888.

See under XXIV., page 141.

ORGANIC CHEMISTRY.—QUALITATIVE.

Hydrogen Peroxide, New Test for. A. Bach. Chem. Zeit. 19, 1895, 37.

The reagents are a solution containing 0.3 grm. potassium bichromate and 0.25 grm. anilin per litre, and a 5 per cent. solution of oxalic acid. In applying the test, 5 c.c. of the solution under examination are mixed with 5 c.c. of the first-named solution and one drop of the second; the presence of hydrogen peroxide is revealed by the occurrence of a violet coloration, the reaction being sufficiently sensitive to detect one part of H_2O_2 in 1,000,000. Neither the oxygenated compounds of nitrogen, nor the foreign bodies occurring in vegetable saps, exert any influence on this reagent.—C. S.

Primary and Secondary Fatty Nitro-Compounds, Reaction for. M. Kononoff. J. Russ. Chem. Soc. 27, 453—455.

Ferric chloride gives a bright red colour with primary and secondary fatty nitro-compounds in benzene solution, especially when shaken up with a single drop of alcoholic potash solution. In this way 5 c.c. of a solution of α -phenyl-nitropropane containing one part in 14,000 of benzene gave a distinct coloration after one hour.—J. W.

Saccharose, Characteristic Reaction for. G. Papasogli. J. de Pharm. et de Chim. [6], 2, 429.

A FEW drops of a 5 per cent. solution of cobalt nitrate added to an aqueous solution of saccharose and followed by a slight excess of 50 per cent. sodium hydroxide, produces a beautiful and fairly persistent deep violet-amethyst colour. Glucose, on the other hand, gives a blue coloration, quickly turning to a pale dirty green; but in mixtures of the two sugars, this reaction is insufficient to mask that due to saccharose, even when the latter is only present in the proportion of 1 to 9. The saccharose reaction being unaffected by the presence of alcohol, caramel, or glycerin, it may be employed for wines decolorised by animal charcoal or sub-acetate of lead.

The transient blue coloration due to lactose does not prevent the development of the characteristic violet of saccharose, and the method is thus suitable for testing for the latter in condensed milk. The same applies to mixtures of saccharose and honey. The colour produced by this latter is blue, changing almost instantly to pale green. Gum arabic, however, gives a permanent blue, masking the saccharose reaction, wherefore this substance when present must be precipitated by sub-acetate of lead before the test is applied; and dextrin—also giving a blue coloration—requires to be thrown down by baryta and ammoniacal lead acetate.—C. S.

Absinthe, Detection of Adulteration in. G. Nivière and A. Hubert. Moit. Scient. 1895, 566.

THREE varieties of absinthe are produced commercially, containing respectively 72, 60, and 50 per cent. of alcohol. Of these the weaker kinds, especially that at 50%, are more particularly subject to adulteration. In the manufacture of inferior absinthe, the plant (*artemisia pontica*) to which the characteristic colour of the genuine article is due, is in great part replaced by *veronica* and *nettle* (ortie), the colour of the product, which is somewhat too yellow, being corrected by the addition of blue, or a mixture of blue and yellow dyes. The property of yielding a turbid mixture with water, possessed by genuine absinthe, is imitated by addition of gum benzoïn, guaiacum, rosin, &c. The following methods serve to detect such additions:—

Colouring Matters.—20 c.c. of absinthe are evaporated on a water-bath, and the residue repeatedly treated with small volumes of chloroform until the extracts pass off colourless. The residue is heated to expel chloroform, and dissolved in water. The resulting solution should be colourless, or nearly so. A decided olive-green tint indicates the presence of artificial colouring matters. Light blue (bleu lumière), if present, may be extracted from this solution (previously saturated with salt) by amy! alcohol.

Matters precipitated by Water.—100 c.c. of sample are diluted with 300 c.c. of water and distilled until the volatile

oils, &c. are completely expelled. The residue is evaporated to a syrup and extracted by chloroform. The weight of extract obtained by evaporation of the chloroform solution should not exceed 0.5 grm. per litre. If greater, the sample may be tested for resins by Halphen's process.

—H. T. P.

ORGANIC CHEMISTRY.—QUANTITATIVE.

Cellulose, Quantitative Estimation of. G. Lange. Zeits. angew. Chem. 1895, 561.

A RESTATEMENT of the method published by the author in 1889 (Zeits. Physiol. Chem. 14, 283), and based upon the observation of Hoppe-Seyler (*ibid.* 1384) that "cellulose is not attacked by heating with the strongest alkalis at 200°."

The following are the conditions now recommended for the process:—The heating (Schmelzen) is carried out in an unglazed porcelain crucible; 5 to 10 grms. of the substance are mixed in the crucible with three parts of sodium hydrate and an equal weight of water. The crucible is gradually heated in an oil-bath to 170°—180°, and kept at that temperature for about one hour. After cooling, the contents are treated with water, and the alkaline solution is acidified. It is then again rendered alkaline, the alkali dissolving "non-cellulose" compounds precipitated together with the cellulose. After purification with water, alcohol, and ether, the cellulose is dried and weighed. It is then burned and the ash constituents determined. The difference of weight represents the cellulose. The process is stated to give concordant results, and in substantial agreement with those of other "standard" methods, *e.g.*, the Wende method and those of Holdelheiss and Hoffmeister.

The author proposes to define as cellulose "those constituents of plant structure which resist the action of alkaline hydrates at 180°—200°"—C. F. C.

Mineral Lubricating Oils, Uniform Methods of Testing. D. Hobie. Chem. Rev. Fett u. Harz Ind. 1896, 1—5, 17—22.

THE chief points in respect of which the testing of mineral lubricating oils is, in so far as practical considerations are in question, necessary, are: viscosity, resistance to cold, volatility, specific gravity, presence of suspended matter, free acids, extraneous oils, dissolved resin, soap, asphalt, paraffin, &c.; and in the case of cylinder oils, action on cast iron under the influence of high pressure (6 to 12 atmos.) steam.

For the determination of viscosity the Engler instrument has proved itself efficient under normal circumstances, but the peculiar influence exerted on the thick heavy oils by exposure to heat (see Mitt. k. k. Versuchs. 1895, Ergänzungsheft 1) necessitates occasional modification of the ordinary method. The simplest is to allow a margin of ± 7 to 8 per cent. in the viscosity at 20° C. of such oils as contain solid particles in suspension, or else to make parallel tests after exposing the oil for 10 minutes to 100° C. and -15° C. respectively. The method of shortening the time of the experiment and of testing cylinder oils at high temperatures has been already discussed (see next abstract but one, p. 138).

The "cold test" may either be directed to ascertaining the degree of congelation an oil will assume at a certain temperature, or the temperature at which solidification commences. In the latter case a preliminary series of tests at different temperatures, with a time exposure of 1 hour, will have to be made with the oil in test glasses, and repeated to obtain the correct result. In the other instance the U-tube method described by Martens (Mitt. aus d. k. k. Versuchsanstalt. 1890, 53; this Journal, 1893, 772), with a constant pressure of a 50-mm. column of water for 1 minute, should be adopted.

The fractional distillation of the heavy oils for the purpose of determining their content of volatile constituents being attended with difficulty, it is usual to employ the flashing-point test to obtain an insight into this matter; but comparative estimation of volatility is desirable, and it may be that the object will be attained by proceeding on

the basis of the author's method of evaporating the oil under favourable conditions at various temperatures from 100° C. upwards.

For testing the flashing point, the Pensky close cup, and for specific gravity the Muencke areometer, are useful. A more exact method for specific gravity, by the pycnometer, and the process for determining the coefficient of expansion, are described in the Mitt. aus d. k. k. Versuchsanstalt, 1893, 54 (this Journal, 1893, 919).

The chemical examination and friction testing will be dealt with in a subsequent paper.—C. S.

Petroleum Industry. Importance of Uniform Methods of Testing. L. Gans. Chem. Rev. Fett u. Harz Ind. 1895, [28], 2—3.

Referring to Zoloziecki's proposition (this Journal, 1895, 1038), the author communicates the methods of testing burning and lubricating oils pursued at the Trieste Mineral Oil Refinery. For the first named, Engler's distillation test is used, the results being plotted as curves. Objection is taken to the various modifications of glass stills, on account of the height of the dephlegmators, which is mostly greater than is conducive to efficiency. The density is determined by Kappeller's thermo-areometer at a normal temperature of 15° C. and the formula $d = d' + \frac{2}{3} (t - t')$, in which $t = 15^\circ \text{C.}$, is employed for correction. Colour and flashing point are tested by the Stammer and Abel-Pensky instruments respectively. The ash determination is only resorted to when the burning tests—carried out with 400 c.c. of oil and a Dymar burner with a 23-mm. wick, the height of the flame at the out-let being regulated to 2.5 cm., and the variations noted by the aid of the kathetometer—reveal the presence of salts (chiefly lime and magnesia compounds) calculated to retard the ascent of the oil in the wick.

The lubricating-oil tests are mainly confined to viscosity, flashing point, reaction, and "cold test"; the latter performed in a very primitive manner. Engler's viscosimeter and Treumann's flash-tester are used.

The "sulphuric acid" and "resin" tests are seldom employed. The author considers that no satisfactory method exists for determining the amount of paraffin in these oils, and for mixed lubricants refers to the works of Benedikt and Kunkler for assistance to the operator in deciding the course to be adopted in special cases.—C. S.

Lubricating Oil Testing, Recent Experiences in. Holde. Mitt. aus d. Konigl. techn. Versuchsanstalt, zu Berlin, 13, (6), 253—287.

The Congelation of Dark Mineral Oils.—A number of experiments carried out at the Charlottenburg Institution confirm previous observations made on the increased liability to congelation exhibited in some oils after being heated to various temperatures between 30° and 100° C., a circumstance attributed to the re-separation in a very finely divided condition, on cooling, of the solid particles of asphaltic, pitchy, or paraffin-like matter originally in suspension in the oil; perhaps also to molecular modifications of these bodies at the higher temperatures. In some instances a contrary effect was produced, which is thought to be probably due to the more gradual re-precipitation of added paraffin. The increased liability to solidify is in some cases obviated by filtering off the solid matter in suspension, and a similar influence appears to be exerted by mechanical stirring. To ensure concordance in the results of testing the resistance to cold of these oils by the U-tube method, and at the same time adhere as closely as possible to the conditions to which the oil is exposed in practical use, it is recommended that samples should be taken from different depths in the storage cask, and that one of them should be first heated for a quarter of an hour to 48°—53° C. This procedure will show whether the oil really conforms to the standard of "cold test" it is claimed to attain.

The effect of the presence of water on the congealing point of the oil is the reverse of what might be supposed, retarding solidification to an appreciable extent. Variations in the molecular structure of the oil, or of the molecular tension between water and oil, may be regarded as the cause

of this peculiarity. These results differ from those detailed by Albrecht (Glaser's Annalen, 1893) as having been obtained in tests instituted in some of the oil refineries, so that it is desirable the subject should be further examined.

Improvements in the Construction and Manipulation of the Pensky Flashing-Point Tester for High Boiling Oils.—To remedy a defect, sometimes noticeable in this instrument, viz., the extinction of the test flame before the occurrence of a flash, the addition of a small fixed gas or oil flame near the test flame is recommended. With reference to the proposed employment of an automatic stirrer, it is considered that the complication of mechanism required would be out of proportion to the convenience afforded to the operator.

Simplification of Viscometric Tests with the Engler Instrument.—In order to shorten the time occupied in testing slow-running oils, the operation may be performed with 50 or 100 c.c. of oil instead of 200 c.c., the results, when multiplied by 5 or 2.35 respectively, being concordant with those obtained in the ordinary way.

Viscometric Tests at High Temperatures.—The ordinary form of Engler's tester gives rise to certain inconveniences, when used at high temperatures, in respect of the difficulty of quickly bringing the oil up to and maintaining it steady at the required degree; the escape of oil vapour from the bath; and the liability of fusing the solder generally employed. The former may be overcome by covering the oil-bath with a lid, affixing a dephlegmator, and leaving only a small vent, the size of which will allow the pressure, and therefore temperature, of the steam-bath to be regulated. In this manner, 180° C. (oil temperature) may be reached by the use of aniline, and 200° C. by means of naphthalin. The other defect indicated may be surmounted by using hard solder.

Concerning the viscosity of the cylinder oils, those tested at Charlottenburg appear as a rule to exhibit a less rapid decrease in viscosity as the temperature rises, and although they may vary very much at 50°, they all pretty well approximate at 180° C. to $1\frac{1}{2}$ — $1\frac{1}{3}$ times the viscosity of water. The average flashing-point of the Russian oils was about 220° C., their specific gravity ranging between 0.906 and 0.929 at 20° C., the American oils flashing in the mean at 265° C. and being of 0.883—0.893 sp. gr.

Rape oil, tested for the sake of comparison, on account of its employment to lessen the volatility and increase viscosity at high temperatures, proved itself at 180° inferior in this latter particular to the generality of mineral cylinder oils.—C. S.

Wool-Fat, Contributions to the Analysis of. W. Herbig. Dingler's polyt. J. 297, [6], 135—141 and [7], 160—161.

AFTER summarising various methods employed for the determination of the unsaponifiable matter in fats, and pointing out what he considers to be defects in them, the author proposes the following process:—From 1 to 2.5 grams of the wool-fat are boiled with semi-normal alcoholic potash, as in the ordinary method of determining the saponification equivalent, the excess of alkali neutralised with acid, the whole washed into a beaker with boiling alcohol, the alcohol evaporated, and the fatty acids precipitated with calcium chloride at 70°—75° C. The precipitate is filtered off, washed with dilute alcohol (1 : 20), and dried on the filter *in vacuo*. When dry, it is extracted for 6 hours in a Soxhlet with freshly distilled acetone, in which solvent the author found that the calcium salts of the fatty acids were practically insoluble. After this, the acetone is evaporated, the extract washed into a platinum basin with ether, and the ether evaporated. The residue, which consists of the unsaponifiable matter and that portion of the wax which is not saponified by the ordinary method of saponification, is then dried at 105° C., and weighed.

The results obtained in this way varied from 48.31 to 48.5 per cent. in a sample of South American wool-fat. In New Zealand fat they were 46.17 to 46.44 per cent., and in a Russian sample 37.07 to 37.29 per cent. In each case five determinations were made.

The chief points to be observed are the absolute purity of the acetone (boiling-point 55.5°—56.5°), and the tempera-

ture at which the calcium salts of the fatty acids are precipitated.

In estimating the free and combined alcohols, the author saponifies under pressure (Cf. Lewkowitch, this Journal, 192, 134; and Herbig, this Journal, 1894, 1068), which effects complete saponification of wool fat, precipitates the fatty acids as calcium salts, and extracts them with acetone as described above. The results obtained were:—New Zealand wool fat, 43·66 to 43·94; Buenos Ayres fat, 43·15 to 43·65; Russian 38·72 to 39·10 per cent.

A certain relation was found to exist between the saponification number and the amount of unsaponifiable matter, and by calculating from the difference of the sum of the molecular weights of the unsaponifiable bodies in the ordinary saponification, and those left after the pressure saponification, figures were obtained which agreed well with the differences found by the gravimetric determinations. The Russian fat, however, was abnormal in this respect. With regard to the composition of wool-fat, the author came to the conclusion that, on the assumption that cholesterol constituted the principal part of the free alcohols, the amount of the cholesterol ester of cerotic acid present in American and New Zealand fat was 9·56 and 5·03 per cent. respectively. Other acids of high molecular weight, like cerotic acid, if present at all, were so only in very small quantities. The greater part of the fatty acids present were in the form of readily saponifiable esters. There were small amounts of lower fatty acids down to stearic and palmitic acids. The percentages of free alcohols in the unsaponifiable matter were 37·89 and 38·85 in the case of the American fat, and 41·93 and 41·27 in that of the New Zealand fat.

In order to effect a separation of the fatty acids, their ethyl esters were fractionally distilled *in vacuo*, the fractions saponified, and the fatty acids recovered and purified by crystallisation.—C. A. M.

Soaps, Analysis of. E. Spacht. Zeits. angew. Chem. 1896, 5.

FOR the determination of all foreign matter, the author recommends extraction with alcohol in a Soxhlet apparatus, the soap being contained in a vessel devised for the investigation of butters, and previously described (*ibid.*, 1893, 513). The method economises time, and leaves the insoluble residue in a condition easily available for further separation into its constituents.

Smaller variations of the methods ordinarily practised are proposed for the estimation of the soap constituents proper, the most noteworthy point being the employment of dilute alcohol (50 per cent.) as solvent in the first instance.

The author emphasises the necessity of finally dehydrating the separated fat acids for weighing, in an atmosphere of an indifferent gas.—C. F. C.

Tannin [Quantitative Estimation]. L. Fajans. Zeits. f. angew. Chem. 1895, 16, 471—472.

THE author has investigated the conversion of tannin into oxalic acid by oxidation with nitric acid under various conditions, the object being to ascertain whether a quantitative method of estimating tannin could be devised by studying the different phases of the oxidation analytically. Although he has not yet succeeded in determining the exact conditions needful for the acquisition of quantitative results, his observations point to the possibility of establishing a quantitative method.

In studying the behaviour of tannin towards other oxidising agents, the following observations were made:—On heating tannin in an aqueous solution treated with a small quantity of potassium chlorate, and adding hydrochloric acid gradually to the mixture, decoloration takes place, oxalic acid being formed. Gallie acid, when treated in a similar manner, yields isotrichloro-glyceric acid; nitric acid, however, yields oxalic acid. When a mixture of tannin and potassium ferrieyanide in aqueous solution is heated on a water-bath, and rendered alkaline by the slow addition of potash, oxalic acid is produced. A similar result is obtained on treating tannin with sodium peroxide.—D. B.

Glucose and Invert Sugar, Estimation of, in Solutions containing Lead. Zamaron. Bull. Ass. Chim. 1895, 13, 346.

BEFORE determining the reducing power of sugar solutions containing lead, it is necessary to remove the excess of lead. The author finds ammonium oxalate suitable for this purpose, the excess of lead salt being at once precipitated as insoluble oxalate. Special experiments show that small quantities of ammonia do not affect the accuracy of the results.—J. L. B.

Alcohols and Volatile Acids, Estimation of. E. Duclaux. Ann. de l'Inst. Pasteur, 1895.

THE method is based on the fact that the superficial tension of mixtures of alcohol and water decreases with the alcoholic strength, the result being that the number of drops furnished by a constant volume of liquid passing through the same orifice increases with the proportion of alcohol present. A modification of the author's drop counter, standardised to allow 5 c.c. of water to escape in 100 drops, at 15° C., was employed, the construction being such that the drops were of constant weight. Among the precautions necessary to ensure regularity are keeping the orifice of the delivery tube perfectly free from fatty bodies, and the removal of everything but alcohol from the solution—the latter effected by distillation from a neutral or alkaline liquid to keep back the aldehydes often formed during fermentation.

As a rule, the alcohols occur singly in fermented liquids, the association of two or more, except in very slight proportion, being rare. In this simplest case, the number of drops furnished by the counter, when read in conjunction with the density of the liquid, indicates the percentage of the particular alcohol present, and tables to enable this to be seen at once are given. For example—

	Density.		Number of Drops.
	1 per Cent. of Alcohol.	10 per Cent. of Alcohol.	
Methyl alcohol.....	998	987	104·0 127
Ethyl ".....	998	987	107·0 144
Propyl ".....	998	987	112·0 172
Butyl ".....	998	987	135·0 286
Amyl ".....	998	987	171·5 291

A table of corrections for temperature to a standard of 15° C. is also provided, as well as examples verifying the accuracy of the method. It is furthermore pointed out, that in distilling ordinary alcohol in the usual manner, down to one-third of the original volume of the liquid, appreciable quantities of the alcohol remain in the still-head and adherent to the walls of the condenser; pure butyl alcohol distils more quickly than ordinary alcohol of equal strength; amyl alcohol in aqueous solution also distils more rapidly than ordinary alcohol, but the distillation should be carried very far to ensure that all has come over into the receiver.

When a mixture of two alcohols is in question, their proportion has to be ascertained. If one of them is present in only comparatively small amount, the number of drops obtained will not entirely agree with the density of any of the pure alcohols, but will approximate thereto. Where the two alcohols are present in comparable proportions, some manipulation is necessary, the liquid being diluted with water or distilled until of a certain density or corresponding to a whole degree on the alcoholometer. It is then necessary to prepare a table of the drops furnished by varying proportions of mixed alcohols of the given density. The number of drops will, of course, depend on the instrument used for counting.

It is found that very small quantities of amyl alcohol suffice to considerably increase the number of drops, although without effect on the alcoholometric degree.

In the case (very rare) of mixtures containing three alcohols, the method is not suitable.—C. S.

Fine Spirit, Quantitative Estimation of Small Amounts of Fusel Oil in, by Rose's Method. M. Glasenapp. Zeits. f. angew. Chem. 1895, 657—663.

In a previous communication (this Journal 1894 982), the author has described the precautions which he has found necessary to observe in order to obtain accurate results when employing this method. He now recommends that the reaction tubes be immersed in a water-bath which is kept at a constant temperature, and he has had tubes made which will sink in the bath when they are being used with the proper quantity of liquid, and at the same time remain upright, in order that the amount of chloroform may be read off without disturbing them.

An important point is the cleansing of the tubes; a mixture of equal volumes of ordinary and fuming sulphuric acid is recommended.—A. L. S.

Wine, Estimation of Tannin in. E. Manceau. Bull. de Soc. Chim. 13, 1098—1101.

Four methods for estimating tannin in wine have been employed:—

- (1.) By a standard solution of gelatin.
- (2.) By a solution of ferric chloride.
- (3.) By a solution of acetate of zinc.
- (4.) Girard's method by means of gut strings.

The first three methods always give lower results than the fourth. The figures yielded by the former are moreover dependent on the dilution, on the temperature, and on the proportion of alcohol, acids, and salts. Girard's method is the only accurate one, but unfortunately it is slow, and is valueless for estimating tannin in champagnes which contain on an average 20 mgrms. of tannin per litre. For these wines the author has employed a combination of gut strings and permanganate of potash. About 100 c.c. of wine are placed in a flask with about 1 grm. of gut, in a week the whole of the tannin will have been removed from the wine. A solution of permanganate of potassium is prepared so that 1 c.c. corresponds to 0.2 grm. tannin, and a solution of indigo-sulphuric acid containing 1 grm. indigo per litre.

Two white glass cylinders are taken and into each is poured 1500 c.c. of water and 10 c.c. of indigo solution. To one is added 25 c.c. of the wine which has been freed from tannin by gut, and to the other the same quantity of the untreated wine. Permanganate solution is then added to one until a clear yellow colour is produced and then to the second until the same tint is produced in that. The difference in the number of c.c. of permanganate used will indicate the amount of tannin in the wine. The gut employed is that sold for violins, not oiled, and washed with alcohol, acidulated water, and distilled water.—A. L. S.

Pentosans or Pentoses, Occurrence of, in Beer. P. Mohr. Woch. für Brauerei. 12, 1895, 769—770.

EMPLOYING Tollen's and Flint's method of conversion into furfural and then into its hydrazone, the author finds that Lager beers contain from 4.22—4.51 per cent. of pentoses; Pilsener, 5.93; and Berlin white beer 5.01, calculated on the dry extract. (See also Morris, this Journal, 1895, 14, 690).—J. G. W.

Flour. S. Cerkez. Zeits. f. angew. Chem. 1895, 663—665.

THE author proposes to classify flour according to the amount of fat it contains; the less valuable flours containing the most fat, which is also proportional to the amount of ash. The latter has been used for the same purpose, but the author considers this as being unfair to those millers who use stones for grinding.

In order to estimate the fat expeditiously he adds 5 grms. of flour to 25 c.c. of ether and shakes well, the flour is allowed to subside and 5 c.c. of the supernatant liquid is taken with a pipette and allowed to evaporate in a dish, and the fat which remains is weighed. This number multiplied by 100 gives the percentage of fat.—A. L. S.

Gelatin, Estimation of, in Meat Extracts and Commercial Peptones. A. Stulzer. Zeits. Anal. Chem. 34, 1895, 568—570.

COMPARE this Journal, 1895, 897. The author gives a few additional details and recommends the use of sand instead

of asbestos which was previously employed. The nitrogen in the form of coagulable albumin of section II. of his former paper requires to be subtracted from the amount of albumose nitrogen as the former substance is insoluble in alcohol.—J. S.

Organic Matter, Estimation of, in Water by Potassium Permanganate. V. Skupevsky. J. Russ. Chem. Soc. 27, 500—503.

THE author finds that a natural water always reduces more potassium permanganate when oxidised first in alkaline and then in acid solution, than when oxidised in acid solution from the beginning. He shows that this behaviour is not due to the presence of acid or alkalis such, for these alone or together have no reducing action on the permanganate under the conditions employed. To estimate the total reducing power of the organic matter in water he recommends the following process:—

100 cc. of the water to be examined is placed in an Erlenmeyer flask and to it are added 2 c.c. of a soda solution (2 parts NaHO in 1 part H₂O) and excess (40—50 c.c.) of a standard solution of potassium permanganate (0.33 grm. KMnO₄ per litre). The mixture is boiled for 20 minutes, and then 6 c.c. of sulphuric acid (1 vol. to 3 vols. water) are added, the boiling being continued for 15—20 minutes longer. When the solution has cooled to 50° it is treated with excess of standard oxalic acid (1.26 grm. per litre), and the excess titrated with standard permanganate. The solution is again boiled for 20 minutes with more permanganate, and the quantity remaining estimated as before. If the two estimations agree, the oxidation is complete; if not, the process is repeated.

Should the water investigated be very rich in organic matter, a smaller measured quantity is taken and the volume made up to 100 c.c. with distilled water.—J. W.

Gum contained in Wine. G. Nivière and A. Hubert. Comptes rend. 121, 350.

See under XVII., page 128.

PATENT.

Butter and other Fats, Process and Apparatus for Testing. Emil Jahr, Berlin. Eng. Pat. 20,051, Oct. 24, 1895.

THIS process depends on the property of butter to form an emulsion with water or aqueous solutions, at a temperature of over 31° C., while other fats do not form emulsions under similar conditions. The butter-fat separates from the water after an interval depending on the temperature of the fluids; mixtures of pure butter with other fats separate out at a speed inversely proportional to the percentage of butter present. The test is rendered more distinctive by the addition of bleaching or colouring material, the different fats being bleached or coloured differently according to the length of time they remain mixed up with the water. The apparatus consists of a spoon-shaped instrument in which a given quantity of the fat is measured off, a vessel in which it is melted, a test glass in which the melted fat is mixed with double the quantity of warm water (preferably at 45° C.), and an air- or water-bath (heated preferably to 45° C.), in which the test glass is placed. In the special form of air-bath illustrated by the inventor, the temperature is kept constant by means of adjustable asbestos plates placed between the flame of a spirit lamp and the bath.

—C. A. M.

XXIV.—SCIENTIFIC AND TECHNICAL NOTES.

An Alkali Centenary. Chem. and Druggist, Feb. 22, 1896, 291.

THIS is the centenary year of the establishment of the Leblanc alkali trade on the Tyne. The first works were started at Walker, in 1796, by a partnership consisting of Lords Dundas and Dundonald, and Messrs. Anbone, John Surtees, John Losh, and Wm. Losh. The last-named, who had lived for some time in Paris, and had probably met

Nicholas Leblanc there, was the managing spirit of the concern. The salt duty of 36*l.* per ton was avoided by concentrating together the brine and sulphuric acid, and thereby obtaining sulphate of soda. John Losh, being a good business man, understood the value of advertising, as may be seen from the following announcement, published by the firm, shortly after its formation, in the Newcastle Chronicle:—

Alkaline Salts,

Such as crystals of mineral alkali or of soda, dried crystals of ditto, barilla salts, crystals of vegetable alkali or of potash, are now prepared in large quantities at the works established near Newcastle-upon-Tyne, from whence yarn bleachers, bleachers, soap makers, plate, flint, and crown glass manufacturers may be supplied with the article which suits their respective purposes.

Not until the repeal of the heavy salt duties, however, could the manufacture attain large dimensions. In 1799, the production of soda crystals on the Tyne was about 10 tons; in 1825, over 400 tons; in 1830, over 3,000 tons; in 1840, 13,000 tons; in 1862, 51,000 tons; in 1873, 97,000 tons; and in 1882, it was estimated at 104,000 tons. That year marked the maximum, and the output has since declined considerably, the quantity of salt decomposed having fallen from 188,000 tons in 1882 to 90,983 tons in 1893. The four alkali works on the Tyne in 1830 had risen to 24 in 1873; and these have now very rapidly decreased until five only are in operation on the river now. When the Leblanc alkali trade had attained its greatest growth, there arose in another district the newer form of manufacture—that by the ammonia process—at first on a small scale, but growing with rapidity, so that whilst in 1892, out of 824,000 tons of salt decomposed in the two processes, 519,000 tons were used in the Leblanc industry, in 1894 the total salt decomposed was 795,000 tons, of which the Leblanc process took 134,000 tons. The efforts that have been made to meet the competition have been heroic and prolonged; the adoption of the Weldon “manganese-recovery process” greatly reduced the use of that article; the hand-furnaces were largely replaced by mechanical furnaces; the manufacture of alkali as the chief product of the works was made subsidiary to that of bleaching-powder; caustic-soda manufacture was begun, and in increasing quantity has continued; the salt deposits of South Durham have taken the place of the Cheshire supply; and, greatest change of all, the recovery of sulphur from tank waste has given a new product, pure and valuable, from what was waste in one of its worst forms. Early in this century soda crystals were sold at 60*l.* per ton; they are to-day 2*l.* 2*s.* 6*d.* In 1838, bleaching-powder was sold at about 28*l.* per ton; the medium price to-day is 7*l.* In the cost, too, there have been vast reductions, for, without looking back to the days of high duties, the cost of salt to the chemical-maker on Tyneside is about one-half of that calculated as the cost in 1862.

Carbonado [a Variety of Black Diamond], A Specimen of, from Brazil. H. Moissan. *Comptes rend.* 121, 449–450.

This substance is much used for boring machinery, and when of good quality it is worth about 2*l.* 12*s.* per carat. The present specimen of “Carbonado” was found on July 15th, 1895, in a diamond-bearing district of the province of Bahia. It weighs 630 grms., or about 3,073 carats, and is the largest piece which has been found, 1,700 carats being the weight of the largest recorded find. It is of a good black colour, and its surface is in places smooth, in others pimply. These parts, under a lens, look as though gas had escaped from them whilst in a pasty condition; they are similar to the surface of the microscopic grains of carbon which the author has obtained by the compression, through sudden cooling, of melted silver or iron. The carbon is porous, having lost 19 grms., or 94 carats, in weight during two months since it was exhumed.—J. T. D.

Glucinum, Carbide of. P. Lebeau. *Comptes rend.* 1895, 121, 496–499.

PURE crystallised carbide of glucinum, prepared in the electric furnace, decomposes water in the cold with

evolution of methane, and in all its other properties so nearly resembles the carbide of aluminium (C_3Al_4), that the author attributes to it the formula C_3Gl_4 . In this case the atomic weight of glucinum would be about 14, and glucina must be a sesquioxide, with the formula Gl_2O_3 .—W. G. M.

Glucinum, Carbide of. L. Henry. *Comptes rend.* 1895, 121, 600–601.

The author disputes Lebeau's contention that glucinum is trivalent, and refers to the work of Combes, who showed that the glucinum derivative of acetyl-acetone had the formula $(C_3H_7O_2)_2Gl$, as compared with $(C_3H_7O_2)_3Al$, which was the corresponding aluminium compound; the glucinum carbide also was CGl_2 . The atomic weight and valency of glucinum should therefore be left undisturbed.

—W. G. M.

Manganese Silicide Vigouroux. *Comptes rend.* 121, 771–773.

MANGANESE silicide, of the composition $SiMn_2$, is formed at the temperature of the electric furnace by the direct action of silicon on manganese, or of silicon on manganese oxide, and also by heating in a current of hydrogen a mixture of silica, manganese dioxide, and charcoal. It is a metallic body, very hard and very brittle, unalterable in the air, and easily attacked by dilute acids.—J. G. W.

Nitrogen, Absorption of, by Lithium, in the Cold. H. Deslandres. *Comptes rend.* 121, 1895, 885–887.

THE author has observed that lithium which has been heated in a vacuum at a temperature below the softening point of glass will absorb nitrogen slowly in the cold, as evidenced by the total disappearance of the characteristic bands in the nitrogen spectrum. The bright surface of freshly-cut lithium, like sodium, rapidly tarnishes in the air, becoming covered with a blackish layer, preventing the absorption of nitrogen, whilst the brighter the surface the more rapid the absorption. It is noteworthy that lithium is at present the only substance known which will absorb nitrogen in the cold.—T. A. L.

Glycerose, New Method for Preparation of. Fonges-Diacon. *Bull. Soc. Chim.* 1895, 13, (16–17), 862–863.

THE author prepares this aldehyde by heating anhydrous glycerin and mercuric chloride in a retort on an oil-bath. At 160° a vigorous reaction takes place, calomel is precipitated in abundance, and a liquid distils over having strongly reducing properties. When the distillation has been continued for seven to eight hours, a yellow syrupy liquid, smelling strongly of acrolein, has passed over, which represents about half the weight of the glycerin employed. This liquid, freed from acrolein, is neutralised with sodium carbonate, and treated with benzene to remove oily chlorides. A clear yellow aqueous liquid results which is inactive to polarised light, gives metallic mirrors, and reduces Fehling's solution strongly in the cold. It forms a crystalline osazone, insoluble in cold water, slightly soluble in hot water, and readily soluble in ether, benzene, alcohol, and ethylic acetate. It melts at 131°, which is the number recorded by Fischer for phenylglycerosazone.—J. L. B.

Mercurous Iodide, Action of Alcohol on. M. François. *Comptes rend.* 121, 1895, 888–891.

THE author's conclusions are that boiling alcohol decomposes mercurous iodide, but the decomposition ceases when 100 grms. of the liquid contain in round numbers 0.22 gm. of mercuric iodide in solution. This reaction is reversible, and the inverse reaction stops at the same point. It follows from the facts, that 1 kilo. of alcohol boiling at 95° C. decomposes about 3.15 grms. of mercurous iodide; further, that the alcohol employed in washing mercurous iodide enriches the latter in mercury, and itself contains mercuric iodide; and also that the quantitative separation of mercurous and mercuric iodides by means of alcohol is incomplete.—T. A. L.

A Vanadium-Platinum-bearing Coal. Eng. and Mining J. Jan. 25, 1896, 81.

WE learn from a reliable correspondent that a firm of merchants in London are in possession of some deposits of coal containing vanadium.

The most remarkable point about the coal is that besides vanadium it contains considerable quantities of the platinum group of metals. Altogether some 10 tons of the coal have been shipped to London, and the whole sampled and analysed. Through the coal there are several very thin bands of earthy matter consisting of sand, limestone, &c., apparently an alluvial deposit, and these bands contain varying amounts of vanadium and platinum metals. A ton of this coal has been burnt and the remaining ash was 15 per cent. of the total weight. This ash gave the following analysis:—Metallic vanadium, 2.9 per cent.; platinum metals (chiefly platinum), 0.23 per cent.; oxygen combined with metals, 5.10 per cent.; sand, carbonate of lime, and other earthy matters, 91.77 per cent.; total, 100.

The metallic contents of one ton of coal are therefore 141 oz. of vanadium and 11.24 oz. of platinum metals.

Table showing Value of Ash.

Per Ton of Ash.	Per Cent.	Troy Oz.	Value.
		Per Ton.	Dols.
Vanadium	19.37	958.8	10,000
Platinum	1.53	75.08	1,000

Counting the value of vanadium at 10 dols. to 15 dols. per oz. troy, and 13.50 dols. to 14 dols. per oz. troy for platinum.

New Books.

PETROLEUM. A Treatise on the Geographical Distribution and Geographical Occurrences of Petroleum and Natural Gas; the Physical and Chemical Properties, Production, and Refining of Petroleum and Ozokerite; the Characters and Uses, Testing, Transport, and Storage of Petroleum Products; and the Legislative Enactments relating thereto; together with a description of the Shale Oil and Allied Industries. By ROBERTON REDWOOD, F.R.S.E., Assoc. Inst. C.E., &c., Assisted by Geo. T. Holloway and other Contributors. In two Volumes, with numerous Maps, Plates, and Illustrations in the Text. Chas. Griffin and Co., Ltd., Exeter Street, Strand, 1896. Price 2l. 5s.

This work fills two volumes of large 8vo size, and is dedicated by the author to the memory of his father, the late Prof. T. Redwood. It contains as frontispiece to Vol. I. a Map of the World, showing the petroleum deposits as so far ascertained; Preface, in which full acknowledgment is rendered, both for the help of friends and of the aid of various periodicals and journals of applied chemistry. Next follows the Table of Contents, a List of Plates, one of which consists of the Map already mentioned, whilst another, that of Petroleum-Vapour Flame-Caps, forms the frontispiece to Vol. II. Besides these, there are distributed through the work 14 other plates, including maps showing the distribution of petroleum in Europe, the Bradford Oil-field, and the Caucasian Oilfields. Vol. I. ends on page 403, and contains 136 illustrative wood engravings; whilst Vol. II., commencing on page 404, is continued to page 873, when the work closes with a very complete alphabetical index. There are three Appendices, A, B, and C. A being a Statistical Report; B, one of Tank Steamers and Tank Sailing Vessels employed in the Export of Petroleum; and C, one of Import Duties levied on Petroleum. Vol. II. contains some 191 illustrative wood engravings. The various sections of the work are devoted to the following leading subjects:—I. General Historical Account of the Petroleum Industry. II. The Geological and Geographical Distribution of Petroleum and Natural Gas. III. The Chemical and Physical Properties of Petroleum and Natural Gas. IV. The Origin of Petroleum and Natural Gas. V. The Production of Petroleum, Natural Gas, and Ozokerite. VI. The Refining of Petroleum. VII. The Shale Oil and Allied Industries. VIII. The Transport, Storage, and Distribution of Petroleum. IX. The Testing

of Crude Petroleum, Petroleum and Shale Oil Products, Ozokerite and Asphalt. X. The Uses of Petroleum and its Products. XI. Statutory, Municipal, and other Regulations relating to the Testing, Storage, Transport, and Use of Petroleum and its Products.

ELEKTRO-METALLURGIE. Die Gewinnung der Metalle unter Vermittelung des Elektrischen Stromes. Von Dr. W. BÖRCHERS. Zweite, vermehrte und völlig umgearbeitete Auflage. Mit 188 Text-Abbildungen. 1896. London: Williams and Norgate, 11, Henrietta Street, Covent Garden. Edinburgh: 20, South Frederick Street. Oxford: 7, Broad Street. Price 14s.

8vo volume in paper cover, containing Preface, Table of Contents, 386 pages of subject-matter, and the alphabetical Index. The text is illustrated with 188 beautifully executed engravings and a few plans of installations. The plan of the work will give the clearest idea of its scope, arrangement, and contents. It is as follows:—Introduction. Electrolysis. Electrothermic Work. ALKALI- and ALKALINE EARTH METALS. EARTH METALS. Aluminium and the CERITE GROUP OF METALS. HEAVY METALS. Copper. Silver. Gold. Zinc. Cadmium. Mercury. Tin. Lead. Bismuth. Antimony. Chromium. Molybdenum. Tungsten. Uranium. Manganese. Iron. Nickel and Cobalt. Platinum Metals. To give an idea of the method of treatment adopted in the case of each of the above metals, the following is that followed in the case of GOLD. I. Preparation of the Ore. Washing. II. Solution of the Gold in Metals. III. Purely Chemical Processes of recovering Gold from Ores. IV. Electrolysis.

PRACTICAL STUDIES IN FERMENTATION. Being Contributions to the Life History of Micro-Organisms. By EMIL CHR. HANSEN, Ph.D., Professor and Director at the Carlsberg Physiological Laboratory, Copenhagen. Translated by ALEX. K. MILLER, Ph.D., and revised by the Author. London: E. and F. N. Spon, 125, Strand. New York: Spon and Chamberlain, 12, Cortlandt Street. 1896. Price 12s. 6d.

The author, in his Preface, states that "The investigations brought together in this book of his, treat in the main of the great questions of the circulation in nature of the alcoholic fungi, their relationship to the diseases of beer, the pure cultivation of yeast, and the employment of systematically selected species and races." The work forms an 8vo volume containing Preface, Table of Contents, 272 pages of subject-matter, with 19 woodcut illustrations, and an alphabetical Index. The classification of the text is as follows:—I. PURE CULTURES OF SYSTEMATICALLY SELECTED YEASTS IN THE FERMENTATION INDUSTRIES. 1. Wherein the new advance consists. 2. Hansen's Methods of Pure Cultivation. 3. The Contributions of Previous Investigators. 4. The Practical Results which have been achieved. 5. The Preparation of Pure Cultivated Yeasts on a Large Scale. II. RESEARCHES ON YEASTS. 1. Characteristics of the Saccharomyces. 2. High and Low Yeasts. 3. Investigations on Low-fermentation Yeasts which have been tested in practice. 4. On Variation. 5. Main Result. III. THE PRACTICAL EXAMINATION OF BEER IN THE STORAGE CASKS WITH REFERENCE TO ITS STABILITY. General. The Method and the Experiments. IV. THE TECHNICAL ANALYSIS OF AIR AND WATER FOR MICRO-ORGANISMS. 1. The Practical Results of Hansen's Air Analyses. 2. The Principles of Zymotechnic Water Analyses. V. WHAT IS THE PURE YEAST OF PASTEUR? VI. INVESTIGATIONS ON THE "DISEASES" OF BEER, PRODUCED BY ALCOHOLIC FERMENTS. 1. Introduction. 2. How the Doctrine of "Diseases" in Fermented Liquids was gradually developed. 3. Hansen's Investigations. VI. ON THE PRESENT POSITION OF HANSEN'S SYSTEM OF PURE YEAST CULTURE. 1. The Object of this Review. 2. Low-fermentation Breweries. 3. High-fermentation Breweries. 4. Distilleries and Yeast Factories. 5. Wine, Cider, and Fruit-Juice Fermentations. 6. Retrospect and Concluding Remarks.

BLEACHING AND CALICO PRINTING. A Practical Manual. By GEORGE DUERR, Assisted by William Turnbull. With diagrams, and upwards of 100 dyed and printed

patterns, designed to show various stages in the processes described. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London. 1896. Price 12s. 6d.

8vo volume, containing Preface, in which it is stated that the work comprises in a condensed form the course of lectures annually given by the author to classes of students studying the Technology of Bleaching and Calico Printing. Next follow the table of Contents, list of Illustrations, some 23, with three plates of larger size, and 142 pages of subject-matter, including the alphabetical Index. After the Index follow 19 sheets of cottons, unbleached, bleached, printed, and dyed. The chief subjects treated of are as follows:—I. Bleaching. II. Printing. III. Mordants. IV. Styles of Calico Printing. V. Thickness. VI. Natural Organic Colouring Matters. VII. Tannin Matters. VIII. Oils, Soaps, and Solvents. IX. Organic Acids, Salts. X. Mineral Colours or Pigments. XI. Coal-Tar Colours. XII. Dyeing. XIII. Water. Theory of Colours.

HINTS ON THE TEACHING OF ELEMENTARY CHEMISTRY IN SCHOOLS AND SCIENCE CLASSES. By WILLIAM A. TILDEN, D.Sc., F.R.S. Loogmans, Green, and Co., London and New York. 1895. Price 2s.

THIS small treatise is intended for the guidance of teachers of elementary chemistry, and its keynote, as is indicated in the Preface, is, the inculcation of *accuracy of observation*. An example given as illustrative of the importance of acquiring the true art of investigating complex phenomena, furnishes exemplification both with regard to elementary chemistry and elementary chemical technology. It is that of the changes occurring when a piece of sheet copper is heated in the air, and, as Prof. Tilden shows, it requires for a complete answer observations—(a.) On the iridescent colours first visible; (b.) The black coating which succeeds; (c.) The red lining to the scales, which may be separated on cooling; (d.) The temperature at which these changes occur; (e.) The alteration in weight of the mass; (f.) Changes in the surrounding air, &c. The little work contains 76 pages of subject-matter, illustrated with seven or eight woodcuts, and containing an Appendix, with extracts from the Syllabus issued by the Department of Science and Art, 1895. An excerpt of the contents indicates the general plan of the work. I. Observation, Qualitative. II. Observation, Quantitative. III. Chemical Equivalents. The Law of Volumes. IV. Molecular Weights and Formulæ. V. Atomic Weights. Classification.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

CUSTOMS TARIFF OF NEW ZEALAND.

Board of Trade Journal, February 1896, 174.

(See also this Journal, January 1896, 57.)

Table of Exemptions from Duties of Customs.

No.	Articles.
CLASS V.—DRUGS, &c.	
316	Acids, viz.: boric, carbolic, in bulk; fluoric, muriatic, nitric, oxalic, oleic, pyrogallie, salicylic, sulphuric.
317	Concentrated extracts, or essences in liquid form or preserved in fat, for perfume-manufacturing purposes in manufacturing warehouses, in bottles of not less than 1 lb. in weight.
318	Disinfectants.
319	Drugs and chemicals, viz.: alum, sulphate of aluminium; sulphate of ammonia; anhydrous ammonia; aniline dyes; arsenic; bluestone, or sulphate of copper; borax; catechu; chloride of calcium; nitrate of silver; cochineal; creosote, crude or commercial; glycerine, crude; gum, arabic and tragacanth; gum benzoin; artificial gum arabic; gum dammar; phosphorus; potash, caustic; potash, and chloride of potash; pearlsh; cyanide of potassium; sal-ammoniac; saltpetre; acetate of soda, crude; soda-ash; caustic soda; nitrate of soda; silicate of soda; sulphate of soda; sulphide of sodium; strychnine; sulphur; chloride of zinc; iron sulphates; gall-nuts; turmeric; saffron; nitrous-oxide gas; tree washes; insecticides; maltine; chlorodyne.

CUSTOMS TARIFF OF NEW ZEALAND—cont.

No.	Articles.
320	Essential oils, except eucalyptus; cod-liver oil; oil of rhodium.
321	Horse-drenches.
322	Medicinal barks, leaves, herbs, flowers, roots, and gums.
323	Scrub-extermiator.
324	Sheep-dip; sheep-drenches; sheep-licks.
325	Surgical and dental instruments and appliances.
326	Scientific and assay balances, retorts, flasks, and other appliances for chemical analysis and assay work.
327	Water-hardening chemicals for brewers' use.

GERMAN CEMENT.

Chamber of Commerce Journal, January 1896, 13.

There are some 63 cement works in the whole of Germany. The Rhine is the principal centre for this manufacture, but in the neighbourhood of Hamburg there are three or four in operation for the production of the article. The annual production of Germany amounts to nearly 11,000,000 barrels, giving employment to some 1,800 hands, whose annual earnings amount to some 698,780*l.* (*sic*). The largest customers for this article in Europe are Russia and Norway, and of Transatlantic countries, the United States, Brazil, Chili, and Venezuela. The exportation to Great Britain and British possessions is comparatively small. The following table gives approximately the quantity and value exported to European and other countries:—

Country.	CWTS.	£
Norway	58,500	6,700
Russia	31,353	2,300
United States	1,386,872	168,000
Brazil	416,310	40,200
Chili	131,000	13,000
Venezuela	103,000	9,800

CHEMICAL INDUSTRY IN ALICANTE.

Chemical Trade Journal, February 15th, 1896, 115.

Considering the size and commercial importance of the province of Alicante, the chemical industries occupy a prominent position.

One of the most important is that of soap-making. Of the 29 works that exist, there are 27 at work. These are chiefly situated round the towns of Alicante, San Vicente, Alcoy, Villena, Monovar, Novelda, Elche, Crevillente, and Callera. The combined yearly production of these 27 works is 12,500,000 lb. of soap.

The next most important industry is the extraction of oils. This process is carried out in two ways, viz., by extraction with a chemical solvent and by expression pure and simple in hydraulic presses. There are 27 works in operation in connection with the latter method, the chief of which are situated at Biar, Villenar, Alcoy, Muro, Elche, Elda, Novelda, Monovar, Villajoyosa, and Ces. These

seed-crushing mills employ 200 workmen. The chemical extraction with carbon bisulphide is carried on to a much more limited extent. There is only one works in operation, and that is situated at Alicante. The amount of oil extracted every year is about 500 tons.

There is another branch of the oil trade represented in Alicante in the shape of two petroleum refineries. Their combined annual production is very considerable, being estimated to be worth 14,000*l*. The number of workmen employed is 120. The wages vary from 1*s*. 3*d*. to 4*s*. 2*d*. per day.

UNITED STATES DRUG IMPORTS.

Chemist and Druggist, February 22nd, 1896, 291.

The following figures show the imports of some of the principal drugs into all the ports of the United States during the eleven months from January 1 to November 30 of 1894 and 1895 respectively:—

	1894.	1895.
Argol or crude tartar..... lbs.	23,592,189	26,285,473
Bark (quinine)..... "	2,488,643	1,800,227
Camphor (crude)..... "	1,278,892	1,137,437
Chlorate of potash..... "	1,061,901	4,549,670
Chloride of lime..... "	86,383,850	91,498,222
*Coal-tar colours and dyes..... dols.	1,883,591	2,558,902
*Glycerine..... lbs.	7,300,025	15,040,236
Gum arabic..... "	1,363,168	1,131,808
Opium (crude or manufactured)..... "	708,768	321,927
*Opium, prepared for smoking..... "	66,249	38,948
*Perfumery and cosmetics..... dols.	471,541	561,678
Quinine and other cinchona salts... oz.	9,906,142	1,715,761
*Soap (toilet)..... lbs.	677,690	729,721
*Soda—caustic..... "	40,813,438	62,857,278
Sal soda..... "	22,315,829	7,632,183
Soda ash..... "	254,128,849	258,679,276
All other salts of..... "	16,750,721	9,216,681
Vanilla..... "	154,911	185,272

* These goods are dutiable; the others mentioned in this note are free.

JAPANESE TRADE IN DRUGS AND CHEMICALS.

Pharmaceutical Journal, February 22nd, 1896, 152.

According to Mr. Gerald Lowther's report for the year 1894, drugs, medicines, and chemicals have, for many years, formed a very important item in the Japanese import trade, as there is a steadily increasing consumption in Japan. The values of drugs and chemicals imported for the past six years have been as shown in the following table:—

Year.	Value.
	£
1889	296,608
1890	331,208
1891	370,961
1892	363,760
1893	446,431
1894	393,313

It is stated that in each of these years Great Britain has had a valuable and important share in the trade. The principal items in the import list for 1894 were salicylic acid, bismuth sub-nitrate, amorphous phosphorus, potassium chlorate, sodium bicarbonate, caustic soda, alcohol, and saltpetre. Alcohol, silver nitrate, and salicylic acid were obtained almost exclusively from Germany, whilst caustic soda, sodium bicarbonate, potassium chlorate, and amorphous phosphorus were equally exclusively imported from England.

It will be noted that there was a considerable falling off in 1894 as compared with 1893, and during the first six months of 1895 there was, according to Mr. Ernest Satow, a further decrease in the value of drugs and chemicals imported equivalent to 118,625 dols., as compared with the corresponding period of 1894; but the next three months saw a change, a net increase being shown over the third quarter of 1894 of 206,318 dols. The value of the October trade, which is the latest recorded, is described as having reached the highest total ever attained in any one month by Japan, the total imports being valued at 12,030,656 dols.,

of which drugs and chemicals are credited with 280,314 dols., as against 487,275 dols. for the whole of the preceding three months.

The Japanese import trade may therefore be regarded as having been, during recent months, in an exceedingly healthy condition. The most interesting item in the exports from Japan, camphor, was exported to the value of 1,023,956 dols. during 1894, 649,457 dols. in the first six months of 1895, and 391,438 dols. in the next three months, a constant increase being thus perceptible during the past year. The figures for the previous five years showed a steady falling-off, and the quality of the product had deteriorated; but a guild was formed amongst the native sellers, and other steps have also been taken to effect a much-needed reform in the quality of the drug.

BOARD OF TRADE RETURNS.

SUMMARY OF IMPORTS.

Articles.	Month ending 31st January.	
	1895.	1896.
	£	£
Metals.....	1,640,662	1,681,443

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND
MACHINERY.

APPLICATIONS.

2150. R. Cunniffe. Improvements in and connected with machines for drying brewers' refuse and other materials or substances requiring similar treatment. January 30.

2543. H. H. Lake.—From A. S. Nichols. Improvements in drying kilns, and in the method of operating the same. Complete Specification. February 4.

2859. J. G. Lorrain. A new or improved method of and apparatus for filtering and purifying liquids. February 7.

2925. E. B. Caird and T. J. Rayner. Improvements in surface condensers and coolers. Complete Specification. February 8.

2930. S. H. Wright. An improved method of conveying air or other gases, and of producing vacua thereby, with apparatus therefor. February 8.
2957. H. A. Kent. Improvements in the construction of platinum vessels or apparatus for the concentration of sulphuric acid. February 10.
3063. J. Spittal. Improvements in condensers. February 11.
3112. F. N. Mackay. Improvements in refrigerating or cooling apparatus. February 11.
3141. J. M. Boustead. Improved apparatus for desiccating. February 11.
3196. W. McD. Mackey. Improvements in or connected with apparatus for concentrating sulphuric acid. February 12.
3218. W. A. E. Crombie. Improvements in apparatus for evaporating or drying. February 12.
3315. J. Laidlaw and J. W. Macfarlane. Improvements in centrifugal machines for separating fluids of different densities. Complete Specification. February 11.
3365. H. B. McKenna. Improvements in the treatment of hydrocarbons for the production of crystalline substances, and apparatus for treating and manufacturing same. February 14.

COMPLETE SPECIFICATIONS ACCEPTED.*

1895.

2421. A. A. Robin. Differential low-pressure still for the distillation of volatile and inflammable compounds. January 29.
2452. J. Klein. Graduating or cooling apparatus and processes. February 5.
2717. F. E. Gateke. Method and apparatus for counter-acting, deflecting, and distributing gases and flames in chemical works, furnaces, or the like. January 29.
2722. F. H. Fyelman. Filtering process and apparatus. February 12.
2946. E. L. Pease and Ashmore, Benson, Pease, and Co. Retort for chemical processes. February 12.
4882. V. J. Kuess. Retort for distilling heavy bodies in general, and particularly gum and resin. February 5.
5496. J. B. Elliott. Evaporating apparatus. January 29.
5856. J. B. C. Krohnke. Apparatus for filtering liquids. February 5.
6868. H. Kropff. Apparatus for dehydrating gypsum and other finely-divided materials. February 19.
7286. E. W. Kuhn. Apparatus for sterilising liquids. February 19.
7425. H. Simmonds and J. Delaney. Kilns or furnaces applicable for burning lime and other minerals. February 19.
- 23,585. A. H. Wright. Improvements in bagasse filters. January 29.
- 24,097. W. R. Herring and M. Graham. Apparatus for charging inclined gas-retorts. February 19.
- 24,214. E. Powell. Improvements in furnaces. February 5.

1896.

469. J. U. Askham. Apparatus for separating substances of different sizes or specific gravities.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

1351. J. Hawley. Improvements in the construction of wood grids for gas purifiers. January 20.
1363. W. Beal. Certain improvements in and relating to the mantles of incandescent gas lights. January 20.
1475. R. Harrison. Improvements in and relating to the production of gases and vapour from mineral oils and other hydrocarbons, and in apparatus therefor. January 21.
1502. J. T. Brunner and H. Brunner. Improvements in the utilisation of coke-oven and other rich gases for manufacturing or heating purposes. January 21.

* See Note (*) on previous page.

1521. N. T. M. Wilsmore.—From D. Little. Improvements in incandescent gas or oil lighting. January 22.

1576. L. Denayrouze. Improvements in incandescent lighting with an intimate mixture of gas and air. January 22.
1681. W. H. Wheatley.—From F. Woernle. Improvements in the manufacture of incandescence bodies for illuminating purposes. January 23.
1682. W. H. Wheatley.—From C. Schmid. Improvements in the manufacture of incandescence bodies for illuminating purposes. January 23.
1750. J. C. Mewburn.—From La Société Anonyme du Combustible Intensif. Improvements in the manufacture of fuel briquettes or blocks. January 24.
1817. C. C. Walker. Improvements in apparatus for enriching or carburetting gas. January 25.
1841. P. Stiens. Improvements in incandescent mantles. January 25.
2000. C. Kortwich. Glow bodies for incandescent gas lighting. Complete Specification. January 28.
2269. J. Moeller. Improvements in incandescent gas lamps. January 31.
2332. G. Holdsworth and G. S. Wilkinson. Improvements in apparatus for generating acetylene gas. February 1.
2452. J. Lehmann. Improvements in burners for incandescent gas lighting. Filed February 3. Date applied for February 1, 1896, being date of application in France.
2553. W. Schoning. Improved process for producing fuel from turf or peat. Complete Specification. February 4.
3142. F. S. Thorn and C. Hoddle. A new and improved acetylene gas generator and container. February 12.
3219. E. B. Pym and J. Gore. Improvements in apparatus for use in the manufacture of acetylene gas. February 12.
3324. C. M. Schnander. Improvements relating to the manufacture of fuel blocks. February 13.
3335. T. H. Gittins. Improved fuel. February 14.
3338. J. H. Exley. Improvements in or appertaining to apparatus for the manufacture of acetylene gas. February 14.
3461. G. Isaac. New process for the production of an indestructible incandescent substance for use with illuminating gases. February 15.
3464. J. C. Hall, H. C. A. Dance, and A. R. Hall. An automatic acetylene gas generator. February 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

3351. P. Brentini. New or improved process and apparatus for the manufacture of gas for lighting and heating purposes. February 19.
3424. D. Hancock, J. B. Craig, and A. H. Hancock. Incandescent carburetted air or gas lighting, and apparatus therefor or connected therewith. February 19.
3425. D. Hancock, J. B. Craig, and A. H. Hancock. Carburetting apparatus. February 19.
3187. H. Strache. Process and apparatus for the generation of water-gas from coke, coal, or other fuel. February 19.
6101. L. M. Bullier. Method of rendering acetylene and other gases rich in carbon suitable for lighting and heating purposes. January 29.
6300. A. McDougall. Treatment of coal to adapt it more economic use as fuel and in the manufacture of gas. January 29.
6777. E. Gearing. Acetylene generating and storing apparatus. February 12.
6870. D. W. Sugg. Incandescent gas burners. February 12.
7281. H. S. Elworthy and P. D. Henderson. An improved process and apparatus for the separation of carbonic-acid gas from the products of combustion or other mixed and less soluble gases. February 19.
- 16,502. E. Dueretet and L. Lejeune. Apparatus for use in the production and utilisation of acetylene. February 19.

21,381. J. Roubal. Manufacture of carbon rods for arc lights. February 19.

1896.

771. M. Seipp. Pulverulent and small furnaces. February 19.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

1489. J. Imray.—From La Soc. Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. Manufacture of colouring matters from triphenylmethane-resisting alkalis and dyeing green and blue. January 21.

1645. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of stable double salts of chloride of zinc and the diazo or tetraazo compounds respectively of amidoazo and diamidoazo compounds. January 23.

1956. G. W. Johnson.—From The Chem. Fab. vorm. Goldenberg, Geromont, and Co. Improvements in the manufacture or preparation of the imide of orthosulphobenzoic acid. January 28.

2196. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of direct-dyeing azo colouring matters. January 30.

2446. S. Pitt.—From L. Cassella and Co. Improvements in the manufacture of azo dyes. February 3.

2705. W. H. Claus and A. Ree. The production of blue colouring matters. February 6.

2771. T. R. Shillito.—From J. R. Geigy and Co. Improvements in the manufacture of polyazo colours or dyes. February 6.

2946. Levinstein, Lim., and I. Levinstein. Production of new sulpho-acid and of colours derived therefrom. February 10.

2999. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of sulphonic acids of the meta-amidophenolphthaleines and their alkyl derivatives. February 10.

3000. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of colouring matter from substituted fluoresceines. February 10.

3028. S. Pitt.—From L. Cassella and Co. Improvements in the production of polyazo dyestuffs. February 10.

3035. J. Y. Johnson. From The Chemische Fabrik Griesheim. A process for the reduction of nitro-benzol and its homologues by means of hydro-sulphide of sodium. February 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

6176. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of dyestuff, and materials therefor. February 19.

6328. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture or production of dyestuffs. February 5.

6697. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The manufacture and production of azo dyes of the benzidine and analogous series. February 5.

6967. F. E. Mafat. Process and apparatus for extracting the colouring matter from dyewoods. February 5.

7170. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of dyestuffs from substituted fluoresceins. February 12.

7237. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, and D. A. Rosenstiehl. Manufacture of azo colouring matters, dyeing unmordanted cotton in acid, neutral, or alkaline bath. February 12.

7498. J. Duxbury.—From E. A. Mitchell. An improved "kaki" dye. February 19.

7549. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of new substantive dyestuffs. February 19.

7969. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of direct-dyeing colouring matters. February 19.

21,812. C. D. Abel.—From L. Durand, Huguenin, and Co. Manufacture of new nitrated oxazine colouring matters dyeing with mordants. February 19.

1896.

698. O. Imray.—From The Society of Chemical Industry in Basle. Manufacture of colouring matters dyeing wool green-black to blue-black. February 19.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

1370. F. N. Turney. Improvements in apparatus for degreasing and cleansing wool, cotton waste, and like fibrous material. January 20.

2213. J. C. Anderson. Improvements in and relating to process of and apparatus for the treatment of wool. Complete Specification. January 30.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

6015. J. R. Barlow and H. Duxbury. Manufacture of coloured figure fabrics. February 5.

8053. J. B. Rapetout. An improved process for treating textile materials in order to render them less liable to be spotted or soiled. February 19.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

1375. J. Berry. Improvements in the printing of water-proof fabrics and apparatus therefor. January 20.

1407. J. Y. Johnson.—From E. G. May, Söhne, and Co. Improvements in the production of coloured figures or designs and ornamental effects. January 20.

1618. W. Hirsch. Improvements in the production of designs upon woven fabrics. January 23.

1757. W. B. Silverlock. An improved apparatus for brushing or removing the bronze or other powder from the end of the surface of paper or other material after the paper has passed through the bronzing machine. January 24.

2423. J. Sanders and T. H. Sanders. Improved process of dyeing browns and fawns. February 3.

2840. T. Halliwell and J. Stones. Improvements in apparatus for dyeing, bleaching, or scouring fibrous materials. February 7.

2814. A. H. Brownlow and J. Stansfield. An improved method of dyeing. February 7.

2971. T. Hoyle and Sons, Limited, and J. A. O'Loughlin. Improvements in dyeing yarns and fabrics made wholly or partly of cotton and other vegetable fibres. February 10.

3058. W. Hepworth-Collins. Improvements in machinery and process for scouring, bleaching, dyeing, and otherwise treating yarn and other spun fibrous materials in cops or in similar compact forms. February 11.

COMPLETE SPECIFICATION ACCEPTED.

1895.

2860. C. E. Middleton, F. P. Middleton, and A. T. Middleton. Dyeing apparatus. February 12.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

1417. P. C. Bunn. Improvements in methods of utilising Weldon mud and similar wastes produced in the manufacture of alkalis. January 21.

1458. J. F. Hutcheson. Manufacture of sodic cyanide. January 21.

1667. T. Fairley. Improvements in the manufacture and purification of ammonium nitrate and other salts. January 23.

1668. T. Fairley. Improvements in the manufacture of ammonium nitrate and sodium salts. January 23.

1729. F. Perez. Improvements in or relating to the manufacture of salt. Complete Specification. January 24.

1900. J. J. Holden and H. Baum. Improvements in the manufacture of cyanides. January 27.

1980. H. R. Angel. Improved method for making ferrite and ferrate of soda. January 28.

2021. R. J. Friswell and Brooke, Simpson, and Spiller, Ltd. Improvements in the manufacture of nitric acid. January 28.

2271. F. T. B. Dapre. Improvements in the preparation of chloride of magnesium solutions. January 31.

2489. W. Garroway. Improvements in the manufacture of sodium and potassium silicates, and of nitric and sulphuric acids. February 1.

3131. P. J. Beveridge. Improvements in obtaining chlorine from hydrochloric acid or chlorides, and the recovery of by-products. February 11.

3196. W. McDouneil Mackey. See Class I.

3230. F. L. Bartelt. Improvements in the manufacture and production of polysulphides of potassium and sodium. February 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

3509. J. W. Swan and J. A. Kendall. Manufacture or production of cyanides. February 19.

6711. A. R. Scott and T. Henderson. Purifying acetates. February 12.

7287. J. Raschen and J. Brock. Manufacture of chlorine, and in the treatment of by-products of the said manufacture. February 19.

7288. J. Raschen and J. Brock. Manufacture of ammonia and its salts from nitrogen-oxychlorides or nitrogen oxides. February 19.

7436. H. S. Elworthy and P. D. Henderson. Methods of solidifying carbon dioxide, and of utilising the solidified substance. February 19.

8314. J. Brock and J. Hawliezek. Manufacture of bicarbonate of soda. February 19.

10,412. W. P. Thompson.—From J. Finlay and E. W. Derry. Manufacture of cyanides and other cyanogen compounds. February 19.

18,406. G. B. Baldo. See Class XI.

23,580. C. Kellner. Manufacture or production of metallic cyanides, particularly cyanide of potassium and of sodium. February 19.

23,591. Manufacture or production of alkaline chlorates. February 19.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

1571. T. W. Simpson and W. H. Bradshaw. Improvements in the manufacture of glass bottles, and in apparatus for the same. January 22.

1794. J. W. Onnrod. Improvements in kilns for use in the manufacture of bricks, terra-cotta goods, tiles, and the like. January 25.

1834. J. Jacques and W. E. McCalka. A new or improved manufacture of articles in glass, tile, pottery, metals, and like substances by a process for producing thereon letters, figures, or designs in permanent colours. January 25.

2114. P. Chapuy. An improved process for the manufacture of porcelain bricks and other constructional elements and apparatus therefor. January 29.

3245. The Cleland Pottery Co., Ltd., and R. A. Mathieson. A new or improved appliance for lifting plastic hollow pottery ware. February 13.

COMPLETE SPECIFICATION ACCEPTED.

1895.

4776. F. Gridlin. Producing the appearance of embossed glass. January 29.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

1408. G. L. Falconar. Improvements in the manufacture or production of blocks or slabs for use for flooring, paving, or in step or staircase, or wall construction, and for analogous purposes. January 20.

2114. P. Chapuy. See Class VIII.

2223. F. Turner. Improvements in the manufacture of cement or artificial stone. January 30.

2285. C. W. Bradshaw and H. A. H. Moore. An improved method of manufacturing refined bitumen for asphalt, electrical, and other purposes. January 31.

2451. D. J. J. Froment. Improvements in the treatment of marble and similar stone. February 3.

2613. W. Beer.—From H. Luschen. A new or improved manufacture of artificial marble for building, decorative, and other purposes. February 5.

2614. F. W. Maxwell and W. Beer. A new or improved manufacture of artificial stone for building, decorative, and other purposes. February 5.

2746. E. Buehboldt. Improvements in or connected with paving and paving blocks. Complete Specification. February 6.

2843. H. Stumonds and J. Delaney. Improvements in kilns or furnaces applicable for burning lime, cement, and other minerals. February 7.

3131. W. P. Thompson.—From F. Hasselmann and A. Sonnemann. A new or improved process for impregnating fibrous substances such as wood, peat, or the like. February 11.

3232. J. T. Hanson. A new method of constructing fireproof floors, flats, partitions, and walls. February 13.

3351. G. Viggars. An improvement in the manufacture of bricks and tiles. February 14.

3373. G. H. T. Ferrington. Improvements in tiles for lining walls, ceilings, and other parts, and in the machinery for manufacturing the same, as well as in the mode and means for mounting the same. February 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

6868. H. Kropff. See Class I.

23,981. F. Ludewig. A new or improved composition for preventing the formation or accumulation of moisture, nitre, or acids in or upon walls and other like surfaces, said composition being capable of being made into artificial stones or bricks for building purposes. February 19.

24,674. F. B. Bond. Fireproof flooring, roofing, beams, bressummers, and the like. February 5.

24,898. M. Nahusen. Process for the manufacture of cement and cement-mortar. February 5.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

1438. G. Tomkinson and A. J. Ash. Improvements in furnaces for heating iron and steel billets previously to rolling the same into sheets and plates. January 21.

1454. H. Martin. Machine for discharging residues from retorts in zinc or spelter furnaces. January 21.

1455. H. Martin. Machine for charging retorts in zinc or spelter furnaces with ore or other material containing zinc. January 21.

1462. J. B. Torres. Improvements in extracting gold, silver, and other metals from ores and other compounds. January 21.

1469. E. L. Oppermann. An improved apparatus for effecting the amalgamation of gold and the like metals in ores with mercury. January 21.

1970. R. B. Boulton. The application or inlaying of metal or alloy, or amalgams, when in a softened condition, in or upon any hard substance devoid of life, and which has been formed into any pattern, lines, letters, or designs. January 28.

2049. J. B. Torres. Improvements in extracting gold, silver, and other metals from ores and other compounds. January 29.

2225. H. H. Bush and J. J. Shedlock. New or improved process and means for extracting metals from their ores. January 30.

2327. T. M. Ash and H. N. Weldon. An improved process for plating or coating non-metallic articles with metals. February 1.

2631. S. H. Levi. Aluminium splice. February 5.

2781. F. B. Last and J. R. Wright. Improvements in and apparatus for the manufacture of iron and steel. February 6.

2792. R. Wallwork. Improvements in apparatus for hardening and tempering metals. February 7.

2931. J. S. Wallace and J. Castell-Evans. An improved process for obtaining metals from refractory ores. February 8.

2997. E. J. M. Servais and P. Gredt. Process for the direct production of iron and steel and other metals from their ores. Complete Specification. February 10.

3054. J. Robertson. Improvements in shaping, forging, drawing, solidifying, and squirting metals, and in means and apparatus therefor. February 11.

3086. J. B. Torres. Improvements in or relating to the extraction of gold, silver, and other metals from ores and the like. February 11.

3201. J. B. Torres. Improvements in or relating to the extractions of manganese from ores and the like, and preparations of compounds therefrom. February 12.

3202. E. L. Oppermann. A new or improved process or means for extraction of gold and other such suitable metals in dry crushed ore. February 12.

3209. C. T. J. Oppermann. Improvements in the means of extracting gold or other precious metals from their ores. February 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

1828. J. Miles. Extracting metals and metallic products from ironstone or argillaceous ironstone from coal and its products, burnt or unburnt. February 5.

4027. H. E. Newton. From The Farbenfabriken vormals F. Bayer and Co. Process and means for protecting iron, steel, and like materials from rust. January 29.

5513. L. Ronseau. Furnaces for smelting metals. February 5.

6673. H. J. Ridley. Method and apparatus for coating metal plates with tin, terns, or other metals or alloys. February 5.

7847. W. P. Thompson. From La Société Neo-Metallurgie Marbean, Chaplet and Co. An improved process of manufacturing improved alloys of refractory metals with more fusible metals. February 5.

18,034. H. Leitner. Oxidising lead and lead compounds for the construction of electrical accumulators. February 12.

23,817. R. Baumann. Facilitating the smelting of brass and other metal turnings and similar fine-metal scrap. January 29.

24,803. L. Pelatan and F. Clerici. Means or apparatus for the obtaining of precious metals from ores or materials containing them. February 12.

1896.

244. F. T. Franke. Annealing and tempering furnaces. February 12.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

1401. A. A. Naville, P. A. Guye, and C. E. Guye. Improvements in electrical gas-reaction apparatus. January 20.

1511. F. E. W. Bowea. Improvements in the manufacture of filaments for electric incandescent lamps. January 21.

1559. J. H. Dunn and J. Parsons. Improvements in making gases and steam by electricity. January 22.

1564. D. G. Fitzgerald and C. N. Stewart. An improved process for utilising peroxide of lead in the manufacture of elements for voltaic batteries. January 22.

1575. Siemens Bros. and Co., Ltd.—From Siemens and Halske. A process for the electrolytic production of zinc from its ores. Complete Specification. January 22.

1669. W. Turner. Improvements in or relating to electric batteries. January 23.

1678. W. Digby.—From A. E. Woolf. Improvements in electrodes for electrolytical purposes. January 23.

1905. H. Maxim. Improvements in furnace-blasts, and in process and in means or apparatus for electro-thermally treating materials, for the reduction of metals, production of carbides, acetylene, cyanogen, cyanides, nitrides, and the fixation of nitrogen. January 27.

2285. C. W. Bradshaw and H. A. H. Moore. See Class IX.

2435. C. Buderus and J. Menz. An improved dialytic process of decomposing stable salts and thereby creating electrical energy. February 5.

2594. A. J. Boulton.—From F. Villani. An improved electrolytic process for extraction of caustic alkali and of hydrochloric acid from a chloride. February 4.

2666. J. E. Preston. An improved fluid for use in galvanic batteries and the like. February 5.

2909. L. Fadero and H. Lumley. Improvements in secondary or storage batteries. February 8.

3022. H. H. Lake.—From H. J. Tudor. Improvements in and relating to the electrodes of secondary batteries. February 10.

3091. R. Linde. Improvements relating to the composition of the filling paste of accumulator batteries. Complete Specification. February 11.

3322. J. Fuchs and L. Thiemann. Improvements in electric batteries. February 13.

3359. E. Bailey and J. Dunn. Improvements in electrical furnaces for volatilising metallic and other ores. February 14.

3361. J. Kirkwood. The electro-plating of iron and other metals and alloys and the electro-reduction of metallic iron. February 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

2998. The Cowper-Coles Galvanising Syndicate, Ltd., and S. O. Cowper-Coles. Apparatus for manufacture of copper, zinc, and other metal sheets, strips, or wires electrically. February 12.

4154. The Cowper-Coles Galvanising Syndicate, Ltd., and S. O. Cowper-Coles. Apparatus for use in electro-deposition. February 5.

7364. J. Wetter.—From The Elektrizitäts-aktiengesellschaft vorm. Schuckert and Co. Electrolytic manufacture of alkali chlorates. February 5.

18,406. G. B. Baldo. Obtaining caustic soda, hydrogen, and chlorine by electrolysis of sea water, and in treating the bye-products obtained during such process. February 5.

22,574. C. J. Grist. Manufacture of insulating compositions for electrical purposes. February 19.

24,516. L. Epstein. Secondary voltaic batteries. February 5.

1895.

130. R. J. Gulcher. Electric accumulators. February 12.

XII.—FATS, OILS, AND SOAP MANUFACTURE.**APPLICATIONS.**

2217. J. Jack. Improvements in and relating to the extracting and recovering of oil from fish, fish refuse, or other oil-producing animal or vegetable matters. January 31.

2511. J. Jack and M. Blake. Improvements in and relating to the extracting and recovering of oil from fish, fish refuse, or other oil-producing animal or vegetable matters. February 4.

2896. J. Stockhausen. A new or improved soap. Complete Specification. February 5.

3181. G. B. Hay. Improvements in the manufacture of saponaceous compounds suitable for the relief and cure of perspiring hands. February 12.

3312. W. Hanley. Improvements in the manufacture of soft and other soaps. Complete Specification. February 13.

3328. G. D. Macdonald and The London and Dundee Syndicate, Ltd. Improvements in or relating to the marking of soap tablets, cakes, or bars with indelible colour. February 13.

3329. G. D. Macdonald and the London and Dundee Syndicate, Ltd. Improved means and apparatus connected with and for the marking of soap tablets, cakes, or bars with indelible colour. February 13.

COMPLETE SPECIFICATION ACCEPTED.

1895.

2471. A. Warwick, J. Smith, and P. W. Nicolle. Manufacture of washing powders. February 5.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.**APPLICATIONS.**

1892. J. Ockermüller. Improved anti-corrosive and process of manufacturing same. January 27.

2201. A. J. Boulton.—From L. P. Converse. Improvements in materials or compounds for waterproofing fabrics. Complete Specification. January 30.

2219. C. Sullivan. Improvements in the production of paint. January 30.

2276. P. C. D. Castle.—From The Gum Tragacanth Supply Co. Improvements in or relating to the treatment of and apparatus for separating the husk of locust-bean kernels from the cotyledons. January 31.

2568. J. L. Pollock. Improvements in air- and water-proofing varnishes or compositions. February 4.

2677. H. Birkbeck.—From P. W. Wierdsma and J. Kuipers. The manufacture of a new or improved substance or product suitable for use as a substitute for vulcanite, hard woods, or other hard materials, or for other uses or purposes for which same may be applicable. February 5.

2681. H. Hawkins and S. H. Hawkins. Improvements in the manufacture of pigments. February 5.

2755. J. Barclay. Improvements in the treatment of india-rubber and india-rubber compounds or substitutes for india-rubber. February 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

1882. V. J. Kness. See Class I.

5924. W. Lutwyche and W. B. Lutwyche. Translucent enamel. January 29.

16,398. K. Deney. Pigments or lakes suitable for the manufacture of wall papers. January 29.

17,786. R. A. Sloan.—From The Inch Non-Corrosive Metal Co. Improved metallic paint and method of making same. January 29.

24,063. J. C. Sellars. Compound or material for use in connection with non-oilaceous protective coverings or paints. January 29.

25,009. H. H. Lake.—From T. Benfield. Process of making oxide of lead. February 5.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.**APPLICATIONS.**

1587. M. Hocquet. The manufacture of new compounds or composition from cork and other materials for use as substitutes for wood, leather, and other substances, or for other purposes to which same may be applicable. January 22.

1875. Baron A. von Mansberg. Process for rendering leather waterproof. January 27.

2572. H. L. J. Roy. Process and apparatus for the rapid tanning of hides, applicable also for dyeing and otherwise treating leather. Filed February 4. Date applied for, July 4, 1895, being date of application in France.

2993. A. Zandroni. A new adhesive and agglutinating substance. February 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

1820. C. Marter and I. Levy. Process for treating animal skins. January 29.

7555. A. Sinan, H. Sinan, and E. Gouin. Process for decolorising and clarifying tannic extracts. February 19.

24,950. A. K. Y. Anderson and J. Mackintosh. A process for treating hides and skins in the manufacture of leather. February 5.

XV.—AGRICULTURE AND MANURES, Etc.**APPLICATIONS.**

2542. S. S. Wallace and J. Castell-Evans. Improved processes for the production of nitrogenous and other substances. February 4.

2678. J. G. Wilburgh. Improvements in the treatment of apatite and other mineral phosphates, and manufacture therefrom of products suitable for fertilising purposes. February 5.

2956. D. Cross. Improvements in artificial manures. February 10.

COMPLETE SPECIFICATION ACCEPTED.

1895.

6112. W. Hutchinson and A. H. Knight. Preparation of basic slag for fertilising purposes. January 29.

XVI.—SUGARS, STARCHES, GUMS, Etc.**APPLICATION.**

1960. E. Shaw. Improvements in and relating to boiling sugar and other syrups. January 28.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

23,171. G. Kassner. Separation of sugar from sacchariferous solutions, juices of plants, and the like. February 19.

24,456. C. Hellfrisch. Process for the treatment of potato starch with chlorine under heating. February 19.

XVII.—BREWING, WINES, SPIRITS, Etc.**APPLICATIONS.**

2030. W. Wrenmore. Apparatus for infusing hops. January 28.

2150. R. Cunliffe. See Class I.

2587. A. Myers. Improvements in processes of manufacturing fermented and distilled liquors. Complete Specification. February 4.

2684. B. Rothenbuecher. Improvements in apparatus for producing crushed malt, and a process of producing wort from the said malt. Complete Specification. February 5.

3098. A. J. Boulton.—From The Pabst Brewing Company. Improvements in or relating to the collection and utilisation of air-free carbonic acid gas from fermentation and apparatus therefor. Complete Specification. February 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

3480. A. Rawinet. Apparatus for manufacture or production of malt. February 12.

5329. F. Colley. Manufacture of malt, and malt houses for treating same. February 12.

5780. P. Pavrez. Treating malt and grain in brewing and other operations. February 12.

7286. E. W. Kuhn. See Class I.

24,387. D. Young. From C. Ballock and C. M. Reed. Method and apparatus for purifying and refining alcoholic liquors. February 12.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

1827. M. C. A. Ruffin. Manufacture of an edible fat from cocoa or coprah oil. January 25.

2081. W. F. Maclaren and A. S. Fleming. Improvements in the manufacture of condensed-milk products. Complete Specification. January 29.

2176. A. B. Pinto. Preserving meat by the help of electricity. Complete Specification. January 30.

2709. J. Dunn and W. Dunn. Improvements in treating barley to obtain a new alimentary product. Complete Specification. February 6.

2815. J. Rose. Improvements in the manufacture of butter, butterine, margarine, or the like. February 7.

3090. C. Kellner. Improvements in the reduction of organic compounds. February 11.

3103. A. J. Boulton.—From W. Meadows. An improved food and processes of preparing the same. Complete Specification. February 11.

3130. W. P. Thompson.—From The New Process Food Co. Improvements in and relating to granulated or powdered food extracts. Complete Specification. February 11.

3250. T. Hyatt. Improvements in alimentary substances, in their manufacture, and in putting up or conditioning them for domestic use. February 13.

B.—Sanitary Chemistry.

1555. W. D. Scott-Moucrieff. Improvements in apparatus for the treatment of sewage. January 22.

2063. J. Hamer. Improvements in the treatment of sewage and in apparatus therefor. January 29.

3047. J. B. Petrie. Improvements in the construction of settling tanks or lodges, used in the purification of sewage and other foul waters, and in the clarification of manufacturers' liquid compositions. February 11.

C.—Disinfectants.

1409. A. J. Boulton.—From F. Fritzsche and Co. An improved manufacture of an antiseptic disinfectant. January 20.

1679. W. Digby.—From A. E. Woolf. Improvements in the manufacture of disinfecting, deodorising, and bleaching agents. January 23.

1978. S. Wohle and A. C. Irwin. Manufacture of detergent. January 28.

2197. E. Hermite, E. J. Paterson, and C. F. Cooper. An improvement in the preparation of electrolysed chloride solutions for disinfecting and like purposes. January 30.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1895.

3513. E. Markham. Process of preserving eggs. February 19.

17,844. J. D. Postle. An improved method or process for the preservation and storage of perishable organic substances by cold. January 29.

22,344. A. F. Jara. Method and apparatus for preserving milk. January 29.

24,282. W. P. Thompson.—From M. Braumann and A. Braumann. Preservation of green vegetables and the like. January 29.

24,293. H. J. Haddan.—From E. Freixa. An improved process of manufacture of nitrogenised water. January 29.

B.—Sanitary Chemistry.

1895.

22,545. E. W. Ives. Extracting precipitated sludge or solids from the bottoms of inverted cone-shaped precipitating tanks for sewage or waste water. January 29.

C.—Disinfectants.

2724. M. R. Latham. Improvements in employment of disinfectants. February 5.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

1555. C. Raymond. Improvements in the manufacture of gelatinised paper or other fabrics suitable for the reproduction by printing with fatty inks of writings, drawings, and the like. January 22.

2388. F. W. Hall. Improved apparatus for straining paper pulp and the like. Complete Specification. February 3.

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.

The Annual General Meeting will be held in London on Wednesday, July 15th next. Full particulars will appear in a subsequent issue.

The prices will be as follows:—

To Members (see Rules 25 and 27) who make application with remittance, not later than June 30, 1896.....	Each copy	5s.
To Members (see Rules 25 and 27) who make later application; Libraries, Corporations, and Exchanges on the Society's List, and Past Members (see Rule 30).....	Each copy	10s.
To Subscribers.....	"	12s. 6d.
To others.....	"	15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

MEMORIAL TO THE LATE PROF. HUXLEY, F.R.S.

This Memorial will take the form of a statue to be placed in the Museum of Natural History, and a medal in connection with the Royal College of Science, while the surplus will be devoted to the furtherance of biological science. Donations towards the fund should be sent to Mr. G. B. Howes, Hon. Sec. Huxley Memorial Committee, Royal College of Science, South Kensington, S.W.

MEMORIAL TO THE LATE PROF. PASTEUR.

At a meeting of the Provisional Committee of the British Section of the Pasteur International Memorial, held on March 21st last, Sir Joseph Lister in the chair, it was unanimously resolved, "That application be made for subscriptions towards the erection of a monument to Pasteur in Paris from persons in the United Kingdom, India, and the Colonies, interested in science and the various industries which have been benefited by Pasteur's labours." An Executive Committee was formed consisting of Sir Joseph Lister, Sir John Evans, Sir Henry Roseoe, Dr. Thorne Thorne, and Prof. Percy Frankland (Hon. Sec.). Subscriptions may be sent to Sir John Evans, who will act as Hon. Treasurer, at the Royal Society, Burlington House, W.

ADDRESS TO PROF. CANIZZARO.

At a meeting of Council held on the 23rd inst. it was unanimously resolved to present an address of congratulation to Prof. Canizzaro on the attainment of his seventieth year of age, which occurs on July 12th next. The drafting of the address was placed in the hands of the Hon. Foreign Secretary of the Society.

INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

This Congress will be opened in Paris, possibly at the Hotel "des Agriculteurs de France," on Monday, July 27th next, and will continue for about ten days. All enquiries and adhesions should be addressed to the General Secretary of the Conference, 196, Bd. Magenta, Paris.

LIST OF MEMBERS ELECTED 23rd MARCH 1896.

Andreoli, Gabriel, 147, Coldharbour Lane, London, S.E., Electro-Chemist.
 Barbour, Sam., c/o F. H. Faulding and Co., Adelaide, S. Australia, Manufacturing Chemist.
 Billington, Chas., jr., Wolstanton, Staffordshire, Brass-founder.
 Bird, Jno. B., Minver House, Bateman Street, Cambridge, Manure Manufacturer.
 Brown, Jas., Kimberley Gardens, Bloomfield, Belfast, Ireland, Brewer.
 Burnham, Mather H., Houghton, Lake Superior, Mich., U.S.A., Mining Engineer.
 Clennell, John E., Rand Central Ore Reduction Company, Box 1891, Johannesburg, S.A.R., Analytical Chemist.
 Flammer, E., c/o Dr. Lewkowitzsch, Lancaster Avenue, Fennel Street, Manchester, Manufacturing Chemist.
 Filton-Smith, J., Nerquis, Mold, North Wales, Brewer.
 Gray, Thos., Technical College, 201, George Street, Glasgow, Lecturer in Chemistry.
 Hewitt, J. Theo., Technical Schools, People's Palace, Mile End Road, E., Lecturer.

Littell, Robt. Ballantine, Setanket, Long Island, N.Y., U.S.A., Chemist.
 Lord, Jno. Lloyd, 5, Commercial Buildings, Love Clough, near Rawtenstall, Chemist and Manager.
 Meisel, C. F. A., 44, Strong Place, Brooklyn, N.Y., U.S.A., Chemist.
 Muir, J. Martin, c/o Muir Bros. and Co., Moscow, Russia, Chemical Manufacturer.
 Muir, Wm., 5, Angel Place, Upper Edmonton, Middlesex, Merchant.
 Perkins, Chas. W., 215, Main Street, New Britain, Conn., U.S.A., Chemist and Druggist.
 Piper, Walter E., Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.
 Powter, Philip, Champ D'Or French G. M. Company, Lim., Johannesburg, S.A.R., Mining Engineer.
 Prochazka, Br. Geo. A., 138, West 13th Street, New York, U.S.A., Colour Manufacturer.
 Steel, Fred. W., c/o Fiji Sugar Company, Lim., Tamaqua, Navua River, Fiji, Analytical Chemist.
 Stewart, Robt. Patrick, 37, High Street, Linlithgow, N.B., Analytical Chemist.
 Stubbs, Augustus J., 4, Calle de Luchana, Madrid, Spain, Mining Engineer.
 Tutbill, Jos. B. T., Salem Gas Light Company, Salem, Oregon, U.S.A., Chemist.

CHANGES OF ADDRESS.

Allen, A. H., 10 Park Lane; Broomfield Road, Sheffield.
 Brindley, G. F., 10 Oldbury; retain Journals until further notice.
 Brown, Wm., 1/o Queensland; 44, Warwick Street, Sunderland.
 Burnham, J. C.; on it "Gunpowder Factory" from address.
 Claus, C., 1/o Jeffrey Square; 88, Yeldham Road, Hammersmith, W.
 Colquhoun, L.; Journals to Nobel's Explosives Co., Lim., Perranporth, R.S.O., Cornwall.
 Cook, E. M., 10 Park Place; Room 819, 150 Nassau Street, New York, U.S.A.
 Cowper-Coles, S.; Journals to 39, Victoria Street, Westminster, S.W.
 Crawford, D., 60, Holly Avenue, Jesmond; and (Journals) c/o Langdale's Chemical Manure Co., Lim., St. Laurence, Newcastle-on-Tyne.
 Formoy, J. A., 10 Forest Hill; Chestham, Grange Road, Sutton, Surrey.
 Greaves, J. A. R., 10 Grappenhall; Woodlands Park, Timperley, Altrincham.
 Handy, Jas. O.; Journals to 325, Water Street, Pittsburg, Pa., U.S.A.
 Harzer, C. A., 1/o Billiter Street; 79½, Gracechurch Street, E.C.
 Herzmann, Dr. M., 1/o Hetzgasse; c/o Dr. Auerbach, III. Salzgasse 15, Vienna, Austria.
 Holloman, F. R., 10 Plaistow; c/o Tennant's Agency, San Fernando, Trinidad, W.I.
 Hopkins, Gerald V., 10 Antofagasta; Nicholaston House, Penmaen P.O., Swansea.
 Hutton-Moss, F. R.; Journals to Box 722, Johannesburg, S.A.R.
 Jackman, E. J., 10 Stoke Newington; 60, Belgrave Road, Hford, Essex.
 Kibble, W. Oakes, 10 Buckhurst Hill; G.P.O., Auckland, New Zealand.
 King, C. M., 1/o Godliman Street; c/o C. D'Oyley Mears, 132, Upper Thames Street, E.C.
 King, Sidney J., 10 47; 49, Arundel Square, Barnsbury, N. Lagerwall, Dr. Ivar, 10 Paris; 3, Princes Street, London, E.C.
 Lascelles, J. H., 10 Calcutta; P.O., Delhi, India.
 Leslie, Hugh M.; Journals to Balaghat Mysore Mines, Lim., Oorgaum, Mysore Prov., South India.
 Lowson, J. G. Flowerdew; Journals to Hollycot, Lasswade, N.B.
 Miller, A. R., 10 Hillhead; Cambuslang, near Glasgow.

Ollerenshaw, S., 1/o St. Helens; 96, Davyhulme Lane, Urmston, Manchester.
 Paine, Standen, 1/o Exchange Street; c/o F. B. Bengier and Co., Lim., Otter Works, Manchester.
 Petty, A., 1/o Upper Clapton; 287, Eglinton Road, Shooters Hill, S.E.
 Philip, Arnold, 1/o Edinburgh; Merchant Venturers' Technical College, Bristol.
 Pilkington, G.; Journals to Old Market Place, Bury, Lancashire.
 Powell, A. Ernest, 1/o Fallowfield; Craigowan, Clarendon Road, Whalley Range, Manchester.
 Rhodes, Jas., 1/o Caldercruix; Beech House, Newtown, via Stockport.
 Sefton-Jones, H., 1/o 31; W. P. Thompson and Co., 322, High Holborn, W.C.
 Smith, Jno. W. (of Mass. Inst. of Technology); Journals to 7, Brookfield Street, Roslindale, Boston, Mass., U.S.A.
 Spiller, Arnold, 1/o Canonbury; Gladstone Villa, Sydney Road, Enfield.
 Towner, Rev. G., 1/o Stratford; 7, Suffolk Terrace, Gordon Road, Southend.
 Veitch-Wilson, J., 1/o Wandsworth Common; Wadhurst, Culverden Road, Balham, S.W.
 Wade, Jno., 1/o London; Wyvenhoe, Purley, Surrey.
 Walker, W. Sloane, 1/o Erith; c/o Walker, Lim., Litherland, near Liverpool.
 Waller, Dr. Elwyn, 1/o Columbia College; 440, First Avenue, New York, U.S.A.
 Warner, H. G., 1/o Wandsworth; 45, Mornington Road, Bow, E.
 Whitehead, Jas., 1/o Huddersfield; Roach Place, Rochdale.
 Williams, Thos., 1/o Birmingham; Tolearne, Wendron, near Helston, Cornwall.

MEMBERS OMITTED FROM LIST.

Gibbs, W. T., Masson P.O., Prov. Quebec, Canada, Manufacturing Chemist.
 Moszczenski, J. von, 121, Wayne Street, Jersey City, N.J., U.S.A., Analytical and Consulting Chemist.
 Small, Evan W., Sunnyside, West Park, Newport, Mon., Director of Technical Instruction.
 Sutherland, Jas., c/o British Aluminium Co., Lim., Larne Harbour, co. Antrim, Ireland, Chemist.

Liverpool Section.

UNIVERSITY COLLEGE, BROWNLOW STREET.

Chairman: G. Schack-Sommer.

Vice-Chairman: Eustace Carey.

Committee:

P. Bateson.	E. Scott.
W. D. Herman.	A. Smetham.
C. L. Higgins.	Frank Tate.
F. Hurter.	H. Tate, jun.
C. A. Kohn.	A. Watt.
E. K. Mospratt.	

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:

T. Lewis Bailey, University College, Liverpool.

SESSION 1895-96.

April 1st, 1896:—

Annual Meeting for Election of Members of Committee.
 Mr. J. Beveridge. "The Wood Cellulose Industry of Scandinavia."

Dr. C. A. Kohn. "A Modified Schrötter Apparatus for the Estimation of Carbonic Acid."

May 6th, 1896.—Mr. W. J. Orsman. "Interaction of Carbonic Oxide and Coal Dust."

Meeting held on Wednesday, March 4th, 1896.

DR. GUSTAF SCHACK-SOMMER IN THE CHAIR.

SORGHUM SUGAR MANUFACTURE IN SPAIN.

BY DR. G. SCHACK-SOMMER.

I HAVE great pleasure in bringing before you samples of sorghum sugar which I have brought with me from Malaga. Sorghum has been grown there for several years past from seed procured from America, and the results obtained have been very satisfactory. The seed is sown at the end of March, or not later than the 15th April. The later it is sown the quicker it will grow, but the plant is smaller and thinner than if sown early. By the middle of September the culms are filled with a juicy and saccharine pith which, if squeezed out, will show a polarisation of about 10 per cent., with a quotient of purity of about 66 per cent.

The saccharine strength, however, increases up to the time of ripeness, when it reaches to a polarisation of 18 per cent. with a quotient of purity of about 82 per cent., and the woody matter is then about 12 per cent. The quotient of purity, however, seems to be deceptive in this case, for the manufacturer, who was kind enough to give me the samples which I am showing you here, obtained only 4½ per cent. of first product and 1 per cent. of second product, altogether 5½ per cent. instead of the 7 or 8 per cent. which might have been expected. The relatively low yield, as explained to me, was due to the abundance of gummy matter in the juice, the extraction of which was impossible for want of proper appliances. As, however, the molasses went to the manufacturer's own distillery, and it pays very well to distil molasses in Spain, I think there is no inducement for exerting skill and spending money on experiments, &c. in order to extract more white sugar, and I therefore, do not ask you to accept the above as a final result of what can be done with sorghum as a source for sugar. Before leaving this subject I must not omit to mention that the same plant that goes to the factory is first stripped of its panicles, which are thickly crowded with a very nutritive grain. The seed tops vary from 15 to 25 per cent. of the total weight of the whole plant. It is an excellent fodder, and is also prepared in various forms for human food. The Earl of Winchelsea is going to sow some of this seed experimentally on his Cable farm this year, and I hope to be able to report upon this trial some time in the autumn.

THE ANALYSIS OF CHROME ORE AND FERRO-CHROMIUM.

BY E. H. SANITER.

In August 1895 I read a paper on the above subject before the Iron and Steel Institute; in December last, Dr. Rideal and Mr. S. Rosenblum read a paper before the London Section of this Society (this Journal, 1895, 1017—1019) on the same subject which is largely devoted to showing that the methods advocated by myself are inefficient, and my theory incorrect. A desire to correct this impression and a modification in the methods will, I hope, be sufficient excuse for bringing before you this paper, a copy of which I have also sent to Dr. Rideal.

The modifications recommended by Dr. Rideal and Mr. J. Rosenblum, owing to the laborious grinding of the materials and the increased time of fusion can only be regarded as a retrograde step so far as speed is concerned.

Of the efficiency of the decomposition attained I am not qualified to speak, not having tested them, and I venture to think that the practical demonstration of my method which I am about to give, on comparatively coarse powders, will convince you that it is unimportant whether Dr. Rideal obtained complete decomposition or not by his method. Before proceeding with the demonstration I will read you the description of the methods.

Estimation of Chromium in Chrome Ore.

Time occupied for analysis: $\frac{3}{4}$ of an hour.

Preparation of the Sample.—The sample is moderately finely ground in an agate mortar.

The Capsule.—A nickel capsule is used. This should not be so heavy as to retard fusion. I find the following dimensions suitable:—2 ins. wide by 1 in. deep, weight about 20 grms.; one capsule at a cost of 1s. 6d. lasts for about 50 fusions.

The Method.—3 grms. sodium peroxide and 0.5 gm. chrome ore are weighed into the capsule and thoroughly mixed. The capsule is now held by means of tongs in a good hot Bunsen flame. As soon as the mass begins to melt, a circular motion is given to the capsule to prevent the chrome ore from settling to the bottom; the fusion and shaking must be continued for about three minutes, when the ore will be completely decomposed. The temperature should be just short of visible red; this will give a very liquid melt.

When the capsule has cooled, it is placed in a large porcelain basin and cold water is put into it, which causes the melt to dissolve rapidly, the basin being required to catch any "spits" which would otherwise be lost.

The capsule and dish are now rinsed into a large beaker; the capsule is again half filled with water, which is heated to boiling, and is thoroughly "conched" and rinsed out. The whole is diluted to about 300 c.c. with hot water and made pink with permanganate of potash. 100 c.c. of dilute hydrochloric acid (1 and 1) are now gradually added and the solution boiled till clear, when 150 c.c. of hot water are added and boiling continued for 10 minutes, by which time all the chlorine is driven off.

The solution, about 500 c.c. in volume, after cooling is titrated with ferrous sulphate and bichromate of potash in the usual manner. In this quantity of solution the nickel salts from the capsule do not interfere with the sharpness of the final point of the titration.

Estimation of Chromium in Ferro-Chromium.

Time occupied for analysis: 1 hour.

Preparation of the Sample.—The ferro-chromium is crushed in a steel-crushing mortar until the whole of the sample passes through a sieve of 10,000 holes to the square inch.

The Method.—4 grms. peroxide of sodium, 0.75 gm. peroxide of barium, and 0.3 to 0.5 gm. of ferro-chromium* are mixed together in a nickel capsule; the process is then carried out exactly as in the case of chrome ore, except that a larger excess of permanganate of potash is added to prevent the peroxide of barium during solution reducing any of the chromate.

[The demonstration was then proceeded with, the result obtained by the time the paper was concluded appearing eminently satisfactory to those present.]

The history of the use of peroxides for this purpose has already been sufficiently discussed in the papers referred to, and I only wish further to remark that neither Donath nor Kinnicent and Patterson used peroxide of sodium with the peroxide of barium.

Dr. Rideal, referring on the first page of his paper to peroxide of sodium in the aqueous solution of the melt, says: "In the numerous analyses of chrome ore, ferro-chromium, and chrome steel we have had occasion to make, we have found that an excess of undecomposed sodium peroxide is in almost all cases present in the aqueous solution of the melt."

This does not agree with my experience when the peroxide is fused at the temperature used by me, and this seems to be confirmed by Dr. Rideal himself, as on turning to the next page we find the following in the description of the process for ferro-chromium:—

"The melt easily dissolves in the hot water, the solution obtained being of a deep purple colour, due to the formation

of the ferrate, which is abundantly formed during the fusion. The solution also contains sodium manganate."

We thus see that in this case, presumably a description of the 10 determinations given below, not only was there no excess of peroxide of sodium, but peroxide of sodium was actually added to decompose the manganate and ferrate.

Dr. Rideal criticises the statement in my former paper that "In dissolving the water solution of the melt sulphuric acid could not be used owing to the presence of barium peroxide, and on attempting to use hydrochloric acid it was found that a considerable quantity of chromate was reduced by it." After deep consideration he has come to the conclusion that I meant something quite different, i.e., chromate of barium, instead of peroxide of barium.

As I still believed my statement to be correct I made the following experiments to place the matter beyond doubt:—

Expt. No. 1.—A known weight of chromate of barium was fused with peroxide of sodium and the water solution of the melt was rapidly filtered and washed twice.

The chromate was then determined in the soluble and insoluble portions as follows:—

	Per Cent.
Insoluble chromate.....	51.8
Soluble	48.2

Only a trace of barium was found in the soluble portion.

We therefore see that barium chromate is actually decomposed to a considerable extent by fusion with peroxide of sodium.

Expt. No. 2.—0.3 gm. ferro-chromium was fused with 0.75 gm. peroxide of barium and 4 grms. peroxide of sodium. The water solution of the melt was filtered and washed twice. The washing was not continued further as it was noticed that the hot water was decomposing the barium peroxide, as shown by the evolution of gas. The chromium was then determined in both portions.

	Per Cent.
Chromium in insoluble portions	6.08
.. soluble ..	56.12
Total	62.20
Chromium present	62.195

Decomposition was quite perfect in three minutes.

This experiment shows that chromate of barium is not formed as suggested by Dr. Rideal, or that if formed to a slight extent it is probably due to the decomposition and solution of the peroxide of barium by the hot water solution, although it is very probable that the chromate found in the water insoluble residue was due to the incomplete washing. This experiment also gives indirect evidence of the presence of peroxide of barium in the residue.

No chlorine was liberated on treating the water insoluble residue with dilute hydrochloric acid, and yet no undecomposed ferro-chromium was found; Dr. Rideal's discovery, that nascent chlorine assists in its solution, is therefore superfluous.

Expt. No. 3.—Similar quantities of ferro-chromium and peroxides as in No. 2 Expt. were fused. The water solution was then boiled for 10 minutes, as directed by Dr. Rideal, to decompose all peroxide of sodium, and diluted to 300 c.c. with hot water, 100 c.c. of dilute hydrochloric acid (1 and 1) were then added and boiling continued; as soon as the solution cleared a further quantity of 150 c.c. of water was added and boiling continued for 10 minutes. After cooling, the solution was titrated in the usual way. Although there was no undecomposed ferro-chromium, it was found that a considerable reduction of the chromate had taken place, as shown below:—

	Per Cent.
Chromium present	62.195
.. found.....	58.750
Showing a reduction of	3.445

This shows that the reduction of chromate can only be due to the action of the hydrochloric acid on the barium peroxide present in the residue, as suggested by Dr. Clark in the discussion on my previous paper.

* I prefer to use such a quantity as will not require more than about 0.6 gm. of iron (in the ferrous state) to reduce the chromate in order to avoid the excessive green colour, which interferes with the titration.

The following analytical results indicate the capabilities of the method :—

Chrome Orc.

	Chromium, per Cent.
Clark's magnesia method	27.40
Stead's tribasic	27.45
Sodium peroxide	27.50

Another sample of chrome ore containing 37.81 per cent. of chromium was completely decomposed in three minutes.

Ferro-Chromium.

	1st Sample.	2nd Sample.
	Chromium, per Cent.	Chromium, per Cent.
Stend's tribasic method.....	26.37	26.93
Sodium and barium peroxide method.....	26.30	26.93, 26.90, 26.96

3rd Sample.

	Chromium, per Cent.
Independent chemists, gravimetric method....	62.25
" " sodium and barium per-	
oxide method.....	62.20
The author, sodium and barium peroxide	
method.....	62.195

In conclusion, I have to thank Mr. T. H. Byrom for his kindness in assisting me with the demonstration this evening.

DISCUSSION.

Dr. S. RIDEAL and Mr. S. ROSENBLUM sent the following comments on the paper:—

In its present form, we should imagine that Mr. Saniter's process can be made to furnish good results, but one must not forget that there are already some 20 or more different processes for the analysis of chrome ores, of which the same may be said. In selecting a standard process from this great variety one must be guided by the consideration: which of the processes affords the greatest economy as to time and work, and is the most logical from a chemical standpoint? As regards the time necessary for the analysis, Mr. Saniter's method leaves nothing to be desired. With respect to the grinding of the material, Mr. Saniter regards our suggestion, that fine grinding is essential, as a retrograde step. We can only repeat what we said in our paper, that we never succeeded in decomposing a moderately finely-ground chrome ore in one fusion, but that sometimes two or three additional fusions were necessary, and that therefore fine grinding was an economy in time. Mr. Saniter's notion of the term moderately fine may be different from ours and, therefore, we will not further insist upon this point.

We cannot understand how Mr. Saniter obtained such good results by his old method, as the undecomposed peroxide of hydrogen must have reduced some of his chromate, a fact which he seems to have overlooked. If as Mr. Saniter contends there is no undecomposed sodium peroxide in the solution of the melt, how is it that in his final modified process he recommends the addition of permanganate of potash and hydrochloric acid? This modification is obviously intended to decompose the sodium peroxide; but it seems to us that it is a longer and more inconvenient method, owing to the presence of chlorine, than the one suggested by us, which consists in boiling the solution for 10 minutes before the addition of acid. We have proved that 10 minutes boiling is sufficient to decompose 1 gram. of sodium peroxide.

We are glad to notice that Mr. Saniter confirms our statement as to the interference of nickel salts in the final point of the titration in his original process, and submit that our method of filtration of the nickel oxide is preferable to that now suggested by him of relying on dilution to obviate this difficulty.

In the analysis of ferro-chrome the addition of barium peroxide is still, in our opinion, useless, and at the same time complicates the process by necessitating the introduction of Stead's process. We would further ask Mr. Saniter

why he preferred hydrochloric acid to sulphuric acid for the solution of undecomposed barium peroxide. This could hardly be due to the interference of barium sulphate in the end titration, as this precipitate is formed in any case in this process by the addition of ferrous sulphate. If the insoluble residue is barium peroxide and not barium chromate, as we suggested, then the addition of acid would liberate hydrogen peroxide, and re-oxidation by Stead's process would become necessary. Again, if barium chromate was absent the barium peroxide could be more conveniently removed by filtration. The reduction, in our opinion, is due, as in the former case, chiefly to the action of the acid upon undecomposed sodium peroxide; and as barium chromate is certainly present in the residue, the addition of hydrochloric acid is necessary for its solution. Although Mr. Saviter has attempted to prove the absence of barium chromate by fusing sodium peroxide with barium chromate, we have proved that barium peroxide fused with sodium chromate is converted into barium chromate, and this is what really takes place in fusing a ferro-chrome with the two peroxides.

When the ferro-chrome was not finely ground we found some of it was left undecomposed after fusion by Mr. Saniter's barium peroxide method, but that when the hydrochloric acid and permanganate was added the chlorine formed brought this into solution. In our paper on this subject this point has been misprinted. We satisfied ourselves that in the barium peroxide process, the chromium exists after fusion in three conditions, viz., sodium chromate, barium chromate, and a small portion of unaltered ferro-chrome (if the substance is not sufficiently finely ground), and we determined their amounts by a method, the details of which can be given. When we add sodium peroxide to decompose the ferrate and manganate formed, we do this in order to ensure a *larger* excess of sodium peroxide, and Mr. Saniter must not conclude that we are ignorant of the fact that it is already present.

Dr. C. A. KOHN asked Mr. Saniter whether the sodium peroxide he used was free from iron. He had found that it contained a considerable amount of iron, and was not available for complete analysis of chrome iron-ore. Also, had Mr. Saniter tried the decomposition of chrome iron-ore electrolytically in presence of caustic potash, and, if so, how did the results obtained compare with those got by the method described.

Mr. G. WATSON GRAY said that in the December number of the Journal he was astonished to find that Dr. Rideal and Mr. Rosenblum mentioned that the higher classes of chrome ore were more troublesome to decompose than the lower. His experience was the reverse. There were samples of the lower qualities that decomposed very readily, and samples of the higher qualities that decomposed equally readily, but the samples that took the most time and patience were probably the lower class chrome ores which were on the market, and the sample mentioned by Mr. Saniter as showing 27.49 per cent. was one of the very worst to decompose.

With regard to the filtering of the manganese, iron, and nickel oxides he had not noticed that their presence was any more objectionable than in the case of testing a manganese ore, where bichromate solution was used. If the solution was too strong it certainly interfered with the clear perception of the final point, but those who were accustomed to make determinations of peroxide or total manganese by means of ferrous sulphate and bichromate were well aware that if the solution was reasonably dilute, there was no trouble in arriving at the final point, and, when a small amount of copper or nickel was present, trustworthy results could readily be obtained: so that to occupy time in filtering off the insoluble oxides of iron, manganese, and nickel appeared to be a great waste of time without any counterbalancing advantage. The amount of nickel that came from the crucible he used was certainly not worth taking into consideration, the crucible having already stood about 100 fusions and being still in good condition.

The method, as given by Mr. Saniter, worked equally satisfactorily in his (Mr. Gray's) hands. When he first used peroxide of sodium (about 12 months ago) he did not get good results, but the failure appeared to be in the

mode of heating, as he then used ore much more finely ground.

The amount of "spits" with the peroxide method did not appear to be more than what he should expect, if he simply used caustic soda. When using Dr. Clark's original method, it was necessary to cover over the dish to prevent loss when dissolving the melt in warm water.

Referring to Dr. Kohn's question about the presence of iron in peroxide of sodium, he (Mr. Gray) had found varying amounts, as well as other impurities, such as silica and phosphorus. He therefore thought it desirable to pass the peroxide through a fine sieve and then estimate the impurities, if it was intended to be used for any other determination than chromium.

Mr. SANITER, in reply to Dr. Kohn, said he had analysed sodium peroxide completely, but could not state from memory how much iron it contained. There was only a small amount of sulphur and silica and a trace of phosphorus. In doing a complete analysis of chrome ore or ferro-chrome, he always did a blank analysis along with it, to check the impurities.

With regard to the electrolytic method he had no experience; these methods were generally too complicated for ordinary use. He was quite in accord with Mr. Gray in finding the richer chrome ores the more readily decomposable; he agreed also that with ferro-chromes, in the lower percentages, the oxide of iron formed impeded the reaction, but nevertheless the method had been found to work perfectly on ferro-chromes containing only 10 per cent. of chromium. He also believed in using two different methods in important cases as a check on each other, when two good methods were available, such as those of Dr. Clark or Mr. Stead.

Dr. Rideal stated that he (Mr. Saniter) had modified the methods; that was true, but the modifications were not vital, the methods as given last year worked perfectly. He found no reduction of chromium, but he considered, when it was pointed out by Dr. Clark in the previous discussion, that an excess of peroxide might sometimes be present, and he therefore modified the method accordingly. Dr. Rideal said that he (Mr. Saniter) confirmed his statement that nickel salts interfered with the final point in the titration. It was a well-known fact that nickel salts interfered in concentrated solutions, and for that reason he had always worked with a dilute solution as stated. In preference to simple dilution Dr. Rideal preferred a tedious filtration and washing. It was quite possible that with the prolonged fusion (15 minutes) recommended by Dr. Rideal so much nickel might be obtained from the crucible as to render filtration absolutely necessary.

Dr. Rideal after suggesting a reason, which proved to be incorrect, as to why sulphuric acid could not be used to dissolve the water insoluble residue of the melt containing barium peroxide, now asked for an explanation; he (Mr. Saniter) would give him the facts; the sulphuric acid would not dissolve the water insoluble residue, the reason for which was sufficiently explained by the experiments detailed. Dr. Rideal still doubted the presence of peroxide of barium in the melt, but that also he considered conclusively proved by the experiments in the paper; further, by fusing sodium chromate and barium peroxide together it was attempted to prove that chromate of barium was formed during the decomposition of ferro-chrome; some chromate of barium may have been obtained under the conditions of the experiment, because most reactions were reversible by reversing the relative quantities of the reacting materials or omitting one, as in the present case, no peroxide of sodium being present, which is used in large excess during the fusion.

Dr. Rideal also stated that he had found a portion of the ferro-chrome to be dissolved by the chlorine liberated. In the first place, it seemed a matter of relatively small importance whether the solution was effected by chlorine or otherwise, so long as all the chromium was obtained in solution in the form of chromate. But putting that aside, the statement was so interesting that he had made an experiment to see if he could dissolve ferro-chromium in this way with nascent chlorine. Finely powdered ferro-chromium was mixed with a large excess of

permanganate of potash crystals and excess of hydrochloric acid was added; it was found, however, that under these conditions no more chromium was dissolved than with hydrochloric acid alone. He might say with regard to the method itself, that during the last five or six days they had tested 25 samples of ferro-chrome coming in in the ordinary course of daily work. These had varied from 11 to 33 per cent. of chromium, and in no case had there been any difficulty. Only yesterday a sample of ferro-chrome was taken, pounded, and analysed in three-quarters of an hour.

MR. GEORGE E. DAVIS IN THE CHAIR.

RECENT DEVELOPMENTS IN THE MANUFACTURE OF CHLORATES.

BY J. GROSSMANN, PH.D.

On the 9th January 1882, the late Walter Weldon published a paper entitled "On some Recent Improvements on Industrial Processes," in which he completed the history of the manufacture of chlorates up to that date. He there gives first a history of the origin of the chlorate of soda industry, and then proceeds to give an account of the methods patented by Mr. Pechiney, of Salindres, for its manufacture; he also incidentally mentions that a certain amount of danger attaches to the attempts which have been made to utilise the mother-liquor from chlorate of potash by treating it with hydrochloric acid. He further gives an account of the process of separating calcium chloride from calcium chlorate by the action of cold, as designed by Mr. Pechiney. But his account, as far as these points are concerned, is really an account of the development of these industrial processes in France; and as the most important of them, that of manufacturing chlorate of soda, originated to the best of my knowledge in England, though I have no doubt that Mr. Pechiney discovered it quite independently, I will first give an account of my work on that salt as carried out between the years 1876 and 1878.

Early in 1876, when I was chemist to Messrs. Jos. C. Gamble and Son, of St. Helens, I received from them samples of chlorate of soda such as were then in the market, and instructions to try and find a method for manufacturing these articles. On examining the samples I came to the conclusion that they were made from chlorate of potash by two processes, viz., by the action of tartaric or silico-fluoric acid. As the price was then about 2s. 6d. per lb., I saw a liberal margin even for the tartaric acid process, and worked this process out, recovering the tartaric acid and bringing the cost to somewhere about 1s. per lb. Unfortunately by that time the price of chlorate of soda had gone down to 1s. 6d. or 1s. 9d. per lb., with a prospect of further reduction if any more were thrown on the market. In 1877, Colonel Gamble, the head of the firm, suggested

that I should try whether, on boiling down a mixture of salt and sodium chlorate in solution, the salt would separate out. On making this experiment I found that the salt did actually separate out, and it then became only a matter of detail to establish the manufacture of chlorate of soda from crude chlorate eistern liquor. I precipitated the latter by carbonate of soda, and boiled down, fishing out the salt and crystallising the chlorate of soda from the mother-liquor. It may be of interest to give a description of an operation as carried on in 1878 and copied out from the laboratory book of the Gerard's Bridge Works.

A chlorate eistern was finished without muriates. It was 27½ Tw., and contained per cb. ft.—

Cl as chlorate.....	Oz.
„ chloride.....	14.92
	83.70
	98.62

The proportion of chlorine as chlorate to chlorine as chloride is as 1 to 5.6.

45 lb. of crystallised soda of 98 per cent. $\text{Na}_2\text{CO}_3 + 10\text{Aq}$ were dissolved in water, and the above liquor added to it until only little sodium carbonate was in excess, while steam was passed through and the mixture well stirred. It took about 130 lb. of the chlorate eistern liquor = 1.8 cb. ft. The precipitate of carbonate of lime was dense and settled well. The liquor after settling was drawn off. It was 11½ Tw. cold, and contained per cb. ft.—

Cl as chlorate.....	Oz.
„ chloride.....	7.33
	42.30
	50.23

The proportion of Cl as chlorate to Cl as chloride is now as 1 to 5.85. The quantity of chloride has increased owing to the salt present in the soda crystals. The liquor now occupied 3.7 cb. ft., and contained per cb. ft.—

Chlorate of soda.....	Oz.
Sodium chloride.....	22.70
	70.7

The precipitate of carbonate of lime was washed twice. The first wash-water was 4 Tw., and contained 6.55 oz. Na per cb. ft. The second wash-water was 1 Tw., and contained 1.07 oz. per cb. ft.

All the liquors were mixed together and boiled down in a pot with a steam jacket. When about 48 Tw. (hot), salt begins to fall out. When about 62 Tw. hot (= 69 Tw. cold), the liquor contained per cb. ft.—

NaClO_3	Oz.
NaCl	330.5
	385.0

When about 72 Tw. hot (= 80 Tw. cold), it contained per cb. ft.—

NaClO_3	Oz.
NaCl	420.0
	192.0

The liquor was then boiled down further in the laboratory, filtered, and put away for crystallising. The fished salt was repeatedly extracted with water and the liquor therefrom evaporated to crystallisation. In this way I got—

41.2 oz. crystals of 96 per cent. NaClO_3	Oz.
In the mother-liquor from these.....	38.70
„ rough salt.....	9.59
„ liquor from rough salt.....	4.56
„ salt, second quality.....	3.32
„ „ first quality.....	6.48
„ washings.....	1.88
	1.85
	66.38

Calculated.....	79.50 oz.
Therefore loss.....	16.5 per cent.
Yield.....	83.5 „

The mother-liquor has always very much the same composition. It is about 80 Tw. and contains per cb. ft. about 400 oz. chlorate of soda and from 120 to 160 oz. sodium chloride.

The crystals slightly washed, and not well, dried contain—

NaClO_3	Per Cent.
NaCl	93.86
Moisture by difference.....	3.40
	2.74
	100.00

and a little sulphate and carbonate of soda, but no iron lead, or tin.

The liquors were in this experiment evaporated more slowly than in previous experiments. Some of the salt was a little coarser, but not sufficient to make any difference in the washing out of the salt.

These experiments were finished early in 1879, and I then had also accounted for the loss of 16½ per cent. and satisfied myself that on a large scale the yield would almost be theoretical, and that on re-crystallising the crude crystals very pure NaClO_3 could be obtained, as the following analysis will show:—

NaCl	Per Cent.
Moisture.....	0.03
NaClO_3	0.34
	99.63
	100.00

It was then that Col. Gamble's great experience and technical knowledge gave the real practical finishing touch to the work. He suggested that instead of carbonate of soda, I should use salt-cake for decomposing the chlorate liquors, and this being found to work satisfactorily, Messrs. Jos. C. Gamble proceeded to erect a plant for the manufacture of one ton of chlorate of soda per week at their Hardshaw Brook Works in St. Helens. The question was at that time discussed whether a patent for this process should be taken out, but it was decided not to do so.

In 1881 Mr. Pechiney took out an English patent for that identical process. As Messrs. Gamble had then already been working the process for some time, Mr. Pechiney's patent was practically void. Still it had the effect of making the process known to all, and I am not surprised that under these circumstances Messrs. Gamble, as I am informed, paid Mr. Pechiney a royalty, and thus practically acknowledged his patent. I have never inquired into their reasons for doing so, but from the context it only appears to me a further illustration of that wonderful combination of a sound knowledge of chemistry, engineering, and business methods which have justly raised Col. Gamble to the high position amongst technologists which he so worthily occupies.

It may be interesting to mention that whereas for the first 12 months it seemed almost impossible to sell as much as 50 or even 25 tons per annum, the production in this country at the present date by this process alone is about 500 tons per annum, besides what is made by the magnesium process to be mentioned further on.

I now come more particularly to my own work on chlorates in connection with chlorate of baryta. When I had finished my experiments on chlorate of soda, it occurred to me that it might be possible that a mixture of barium chloride and sodium chlorate in solution would decompose on boiling down in such a manner that salt would separate out, and chlorate of baryta would predominate in the mother-liquor. A small experiment satisfied me that this reaction did take place. I then made a number of experiments on a larger scale: the salt which separated was fished out and washed, the liquor filtered hot and left to crystallise; the first crystallisation yielded crystals which contained 72 per cent. of barium chlorate. On re-crystallising these twice, pure crystals containing only 0.025 per cent. NaCl were obtained. From an entry in the old laboratory book I find that in March 1881, I had established that the composition of the crystals of chlorate of baryta was $\text{Ba}(\text{ClO}_3)_2 \cdot 11\text{H}_2\text{O}$, a matter on which the text-books seemed to be doubtful up to then. A plant was put up at Gerard's Bridge in 1881 for the manufacture of chlorate of baryta. The plant and process have since passed over to the United Alkali Co., who are still carrying it on. The process was not patented, and it is an extraordinary thing, reflecting

great credit on the many chemists who must have been connected with it, that this process has been working for 15 years without becoming known; it was only brought before the public four months ago in the opening address of our Chairman, Mr. Davis. The production of chlorate of baryta in this country by my process amounts to about 30 tons per annum. Its use is almost entirely pyrotechnical, a small quantity being used for making other chlorates in solution, by decomposition with different sulphates.

I next directed my attention to the manufacture of chlorate of ammonium. Before making experiments upon this substance I went to see my friend the late Prof. Schorlemmer in Manchester, but found that even he, whose knowledge was phenomenal, could give me no further information than what was contained in the text-books, viz., that it was likely to be explosive. An experiment made on the small scale showed that on boiling down a mixed solution of ammonium chloride and sodium chlorate, sodium chloride separated out. I then made an experiment on a larger scale; the solution of sodium chlorate and ammonium chloride was boiled down in a steam-jacketed enamelled pan, the salt was fished out, and the hot concentrated solution filtered. I thus, on cooling, obtained a large crop of crystals of ammonium chlorate, NH_4ClO_3 (about 30 lb.); this was well drained, and, for fear of accidents, I placed it in an iron pot and carried it myself into a large empty shed. But within 24 hours it exploded with great violence, knocking a large hole into the bottom of the iron pot. This finished my experiments on chlorate of ammonium, which, but for the unfortunate property of exploding at the wrong time, might be a very useful article in the manufacture of explosives. It is a very curious fact that, of two samples which I took at the same time and placed in sealed bottles, one exploded about six months later, and the other may not have exploded yet, as I have never heard any more about it.

This brings us to the beginning of 1882, when I left Messrs. Gamble to commence business on my own account in an entirely different direction; but before giving a short account of what progress has been made since then in the manufacture of chlorates, I will refer again to the remark made by Mr. Weldon that a certain amount of danger attaches to the process of treating the mother-liquor from chlorate of potash with hydrochloric acid. I had made a number of experiments as early as September 1876 on the laboratory scale, and found that if the mother-liquor is run into the acid and steam passed through at the same time, there is not the slightest danger in this process, and I obtained bleaching powder testing 35.7 by it. I repeated these experiments on a large scale in a Weldon's still, and worked a number of operations, being all the time either in the still-house or on the top of the still. The evolution of chlorine was quite regular, and there was no sign of any explosion. I am particular in mentioning this, as there are so many erroneous statements unfortunately found in our literature, copied from one book to another for generations by the gentlemen who make it their business to write books, that I consider it the duty of every chemist to correct such statements whenever he has the opportunity to do so.

There is nothing to record in the year 1882, except that a patent was taken out by T. W. Bottomley and R. F. S. Molesworth (this Journal, 1882, 67) to make chlorate of soda from chlorate of potash or from crude chlorate of lime liquors by decomposing them with bitartrate of soda. As by that time chlorate of soda was below 1s. per pound, it is not likely that the patentees made a large fortune out of that patent. In 1883 a remarkable patent was taken out by W. Weldon (Eng. Pat. 99) ; it related to, viz.:—"Improvement for the recovery of sulphur from alkali waste." At that time Mr. Weldon was greatly enamoured with Schaffner and Helbig's process, which consists in boiling alkali waste with chloride of magnesium. In order to get magnesium chloride cheap, he proposed—for the first time, as far as I know—to use milk of magnesia instead of lime for the manufacture of the crude chlorate liquors, to crystallise out the chlorate of potash in the usual way, and to use the mother liquors for the evolution of sulphuretted hydrogen from alkali waste. It is extraordinary that a man of Mr. Weldon's experience should have been carried

away by his anxiety to obtain magnesium chloride in solution for the express purpose of Schaffner and Helbig's process so far as to have entirely overlooked the advantages which might be derived from this process for the manufacture of chlorates. At that time Schaffner and Helbig's process must have shown distinct signs of failure: in any case Mr. Weldon did not proceed with the patent. On the 31st October of the same year, however, Messrs. E. K. Muspratt and G. Eichelmann took out an almost identical patent for the express purpose of making chlorates; that is, they proposed to pass chlorine gas through magnesia suspended in water. The chlorate which remained in the mother-liquors was to be liberated by hydrochloric acid, and magnesium chloride and chlorate of potash were thus to be made as it were in one operation. There can be no doubt that this process constitutes one of the greatest improvements that have been made in the manufacture of chlorates, although it has the inevitable objection which all processes have, by which two articles are made at the same time, viz., that it is impossible to determine the exact cost price of each. Moreover, to a certain extent the production of chlorates would have to be regulated by the ability to sell the resulting magnesium chloride. By a further patent taken at the same date the same inventors apply that process to the manufacture of chlorate of soda, decomposing the crude chlorate of magnesium liquor by carbonate of soda or caustic soda.

In a previous patent, August 15th, the chloride of magnesium was re-converted by evaporating the mother-liquors and heating. In 1884, on April 5th, a patent was taken out by J. Wilson, Berwick-on-Tweed (Eng. Pat. 5975), for passing chlorine through a mixture of magnesia and chloride of potassium, and for recovering chlorine, hydrochloric acid, and magnesia by evaporating the resulting mother-liquors and heating them in a muffle furnace. I may briefly mention that in 1885, at the International Inventions Exhibition in London, Messrs. J. Muspratt and Sons exhibited for the first time in this country potassium chlorate and sodium chlorate made by the magnesium process; and Messrs. Gamble exhibited chlorate of soda and chlorate of baryta made by my process.

In 1886, November 6th (Eng. Pat. 14,344), Mr. J. W. Kynaston obtained a patent by which he proposed to remove part of the calcium chloride in the chlorate of potash mother-liquors by boiling the latter with lime. An oxychloride is formed, which crystallises out on cooling, and which he claims to be a very stable compound when suspended in a solution of calcium chloride. I had made similar experiments while at Messrs. Gamble's works, but the results which I got were never satisfactory, and I am afraid Mr. Kynaston has not been able to overcome the difficulties either, as to the best of my knowledge the process is not in use anywhere. In 1887, June 8th (Eng. Pat. 8217), G. H. Bolton, J. R. Wyld, and H. Auer took out a patent entitled "Improvements in or relating to the manufacture of permanganate of soda, or of a mixture of the same with other disinfecting or oxidising matters." They proposed to use chlorine for the purpose of converting potassium manganate into permanganate; chlorate is formed at the same time, and the two salts are to be separated by evaporation and crystallisation. The same inventors took out another patent on July 13th, 1888, entitled "Improvements in the manufacture of permanganates and chlorates," by which they treat a solution of manganate of soda with chlorine, and thus got a mixture of sodium permanganate, chlorate, and chloride in solution, which they evaporate to about 90° Tw. They then add potassium chloride almost equivalent in quantity to the sodium permanganate, and on letting the solution cool permanganate of potash crystallises out. The mother-liquor is further concentrated to 130° Tw., when more sodium chloride can be fished out, and the liquor will yield another crop of permanganate crystals. The mother-liquor from this is treated with sulphuretted hydrogen or a soluble sulphide to remove the manganese, and then contains a mixture of chlorate and chloride of soda, which can be worked up into chlorate of potash or chlorate of soda as required.

On 20th October 1888 (Eng. Pat. 15,097), a patent was taken out by J. R. Wyld, M. J. Hamill, and H. Auer,

entitled "Improvements in or appertaining to the separation of chlorate of potash or magnesium or other similar salt in mother-liquor from solutions thereof."

The purpose of this patent is to subject the mother-liquors from the manufacture of potassium chlorate, in which from 15—20 per cent. of the chlorate is lost, in a suitable apparatus to the action of cold, when about two-thirds of the chlorate in solution will be crystallised out, and can be recovered. This, no doubt, is one of the greatest advances made within the last 10 years in the manufacture of chlorates, but as Mr. M. J. Hammill has given a full description of it in this Journal, March 30th, 1889, it is not necessary for me to enter any further into the details of it. The process is worked very satisfactorily by the United Alkali Company, in St. Helens. On the 16th February 1887 (Eng. Pat. 2786), a patent was taken by Messrs. E. K. Muspratt and G. Eschelmann for "Improvement in the manufacture of chlorates, and the magnesium hydrate suitable for use therein." They propose in this patent to use magnesium hydrate in preference to magnesia, and describe the way in which to prepare the hydrate. On the 16th October 1889 (Eng. Pat. 16,460), D. Gamble, St. Helens, patented as a communication from A. R. Pechiney, Salindres, "Improvements in the manufacture of chlorate of soda." This patent consists in mixing salt-cake, lime, and water, and passing chlorine through the mixture, thus really doing in one operation what had been done in two operations up till then.

On the 19th May 1893 (Eng. Pat. 10,053), A. J. Boulton, London, patented, as a communication from A. Nieske, of Dresden, "Improvements in or relating to the manufacture of chlorates." He mixes the "octagon" liquors with chloride of potassium and then adds sufficient salt-cake to decompose all calcium chloride. He evaporates, fishes out the salt, and crystallises the chlorate of potash from the concentrated solution. There is a guileless remark in that patent, that if it be intended to make chlorate of soda, the chloride of potassium is not to be mixed with the "octagon" liquors; but where in that case the difference comes in between this method and the one worked out in St. Helens, and which Pechiney patented in 1881, is more than I can understand. He also proposes to treat strontium or barium hydrates with chlorine, and convert these into chlorate of potash and chlorate of soda; but neither of these processes are likely to be used much in the near future, nor does the patent appear to me to be particularly strong. A patent was taken out by K. J. Bayer (Eng. Pat. 17,978) under the title of "Improvement in the manufacture of potassium chlorate," the object of which is to recover chlorine lost as calcium chloride in the manufacture of potassium chlorate; and for this purpose oxide of zinc is used instead of lime. Three equivalents of oxide of zinc are mixed with one equivalent of potassium chloride and heated to 98° C. with a suitable quantity of water; chlorine is then admitted. Potassium chlorate crystallises out on cooling. After decantation, the mother-liquor is evaporated to about 60° B., when on cooling a further quantity of potassium chlorate is obtained. Finally, the mother-liquor is evaporated to dryness, with addition of a little hydrochloric acid to decompose any traces of chlorate.

There are two patents relating to the manufacture of potassium chlorate and sodium chlorate from their respective carbonates. The first of these patents, taken out by J. Hargreaves, of Farnworth-in-Widnes, and Thomas Bird, of Cressington (Eng. Pat. 18,526), is entitled "Improvements in the manufacture of chlorates of sodium and potassium." The chlorate is made by passing chlorine into a solution of caustic soda, sodium carbonate, or bicarbonate. The absorbing vessels are specially constructed with agitators. The gas is passed through these, so that the gas enters where the conversion into chlorate is almost completed. During the reaction sodium chloride is deposited, and, where sodium carbonate is used, some bicarbonate. To render all the soda available, agitators are employed. To separate the chlorate from the salt, the contents of the absorber are run off into a filter or centrifugal, steam in either case being forced downwards through the residual mass of chloride. The solution so obtained is evaporated to a strength of 100°—120° Tw. and run into crystallisers.

When the chlorine has to be aspirated through the absorbers by an exhaustor, the exit gases are passed over soda or other suitable medium to remove all traces of chlorine gas that may have passed away unabsorbed.

According to the other patent taken out by T. T. Best and J. Brock, Liverpool (Eng. Pat. 19,189), entitled "Improvements in the manufacture of chlorate of soda," chlorine, preferably diluted by inert gases, is passed into a concentrated solution of sodium carbonate to saturation. The process is preferably conducted at ordinary temperature, and should not rise above 100° F. The cleared solution is concentrated to cause sodium chlorate to salt out, and it is then set to crystallise.

It is evident from the last two patents that the minds of those connected with the manufacture of chlorate are now working again in the direction of using sodium carbonate for the purpose. I must confess that I cannot see any economy in these patents, even if they were taken out for getting rid of unsaleable weak soda ash. Considering that there are practically six equivalents of salt formed for every equivalent of chlorate, I cannot help looking upon these patents as a very expensive method of making salt. In conclusion, I may say that I have not touched in any way upon the electrical methods used for the production of chlorates, as there is at present too little known of them to enable me to give a satisfactory report.

DISCUSSION.

Mr. GRIMSHAW: With regard to the attempt to use zinc oxide instead of calcium oxychloride, Dr. Grossmann did not say whether it was proposed to pass the chlorine into water, leaving the chlorate behind, or whether it was left for someone else to try this process, in which case they would require to be pretty well guarded, as the explosion took place at or near the surface of the liquid, and it was surprising the force which was produced. He endorsed Dr. Grossmann's views as to calcium oxychloride. It was a remarkably suitable compound so long as it was immersed in the mother-liquor, and it was very easily crystallised, but the crystals soon decomposed on coming in contact with the air.

The CHAIRMAN said it was very enjoyable to hear how chemists had gone through fire and water in making these compounds on a large scale. Just before Dr. Grossmann commenced manufacturing them, a certain firm in London started to make chlorate of ammonia, and they proceeded to boil down this liquor in steam-jacketed pans, which resulted in the demolition of the buildings in which the operations were conducted. In this case they did not produce the crystals, whereas Dr. Grossmann had got the crystals, and the explosion followed. With reference to Dr. Grossmann's statement as to using up all the rough chlorate mother-liquors, in his (Mr. Davis's) time at St. Helens these mother-liquors were used up by running them into the acid and passing them into the chamber with a weak bleaching powder, and then taken to the chlorate pipkins and finished off. They soon found it was not safe to continue this process, and the heavy top-stones were removed.

Dr. GROSSMAN, in reply to Mr. Hart, said that Mr. Gamble commenced the chlorate of potash process at St. Helens in 1848. It was considered at the time to be a most unsaleable article—about half a ton a week was made. It could not be made at the price—half a crown a pound. Fifteen years ago a large firm of match makers in this country used five tons a week of chlorate of potash, and they were using considerably more at the present time. In reply to Mr. Grimshaw's remarks about zinc oxide, he had no further information about the process than what was set forth in the specification; and he should think it very unlikely from the properties of zinc chloride, and from the way in which it behaved in boiling down, that the yield would be very great. With reference to the Chairman's remarks as to the explosions in London, he was not aware that anyone had worked at the process at the same time.

Meeting held Friday, March 6th, 1896.

MR. GEORGE E. DAVIS IN THE CHAIR.

ON DESTRUCTORS FOR CONSUMING TOWN REFUSE—THEIR REQUIREMENTS, DEFECTS, AND MODES OF IMPROVEMENT.

BY STEVENSON MACADAM, F.I.D., F.R.S.E., F.I.C., F.C.S., ETC.

THE subject of destructors for consuming the refuse of towns has, in recent years, assumed much importance, owing to an increasing difficulty in getting quit of house-garbage, shop-sweepings, and other offensive matters, all as comprehended under the general title of Police Manure.

The difficulty has arisen partly from a change in the character of the manure. Previously much faecal matter or night-soil was incorporated with the material, but the water-carriage system so largely adopted in cities such as Edinburgh, and the pail system used in many parts of cities and towns in England, have withdrawn much of what was of fair fertilising properties, and have necessarily left the remainder of less manurial value.

Attempts have been made to meet the difficulty of disposal of the material by acquiring the right to old quarries and dis-used brickfields, and depositing the refuse there; but such accumulations of putrescent matter have resulted in being a nuisance alike to the atmosphere in the neighbourhood and to the water drainage from such localities. The authorities of populous places have therefore had to face the necessity of providing other outlets or means of disposal.

The employment of destructors for the purpose is comparatively of modern date, as it was only in 1876—20 years ago—that the first destructor was systematically employed for the treatment of town refuse, and for reducing it to an innocuous residue.

Simultaneously, attempts were made by a process of sorting and sieving the refuse, to deal with it in a satisfactory manner—using the finer portions for compounding a manure with night-soil, fish-remains, &c., and otherwise by classifying the remainder and partially consuming it. But whilst such a mechanical process was somewhat successful as a stage in the operations, and is still kept up in a few places, yet there has been of recent years, and still is, a general agreement of opinion amongst all those who have considered the subject, that the most satisfactory results in dealing with town refuse must be looked for in the treatment of it in well-constructed and well-worked destructors.

The general nature of town refuse collected in populous places is much the same in quality. The main part consists of the contents of ash-buckets, including cinders, coal ashes, refuse vegetables, tea leaves, fish cleanings, and bones, animal debris of all kinds, dead dogs, cats, rats, &c.—not to speak of old tin cans, broken crockery, &c.; then we have the contents of shop buckets, including floor sweepings, cinders, and coal ashes, waste papers, &c.; and further, from certain shops and markets there are putrid meat and fish, decaying fruit, &c., &c. All of these materials, with a little selection and withdrawal of occasional pots and pans, broken fenders, aerated water and other bottles, must be disposed of in the destructor.

Now a good working destructor must be prepared to consume all the organic part of town refuse under three conditions:—

1st. That the inflaming part of the refuse shall be burned into non-smelling and practically innocuous gases;

2nd. That a good cinder shall then be obtained, which will continue to burn and glow, without evolving foul gases; and

3rd. That ultimately a hard, vitreous, or glassy residue shall be obtained, commonly known as clinker, which will be practically non-smelling, and which may be utilised for road making and in cement making.

These conditions necessarily require to be supplemented by the arrestment of all escaping dust by careful working of the destructor proper, and by providing efficient dust chambers for the temporary lodgment of the finer dust.

When all these conditions are properly fulfilled, the refuse from towns may be consumed in destructors without becoming a nuisance to the neighbourhood, either as to smell or dust. These satisfactory results have been attempted in several forms of destructors.

The Fryer's destructor, Fig. 1, was practically the earliest in

Fig. 1.

A, Feed-hole; B, dead hearth; C, fire-bar grating; D, ashpit; and E, main flue to chimney.

use, and the larger number of destructors in operation in the Kingdom are on this plan. Each cell or furnace has a fire-bar grating of 5 by 5 feet, with a dead fire-clay hearth behind of 4 by 5 feet, making altogether a cell area of 9 by 5 feet. The fire-bars have an upward slope from the front towards the back of 1 in 3. When each cell or furnace is properly started, the town refuse is dropped in by a feed opening right down on the dead hearth, where it may lie for a time drying and stewing. It is then raked forward over the cinder on the fire-bars, and active combustion of the lighter parts at once ensues, whilst stewing and combustion of the heavier parts also takes place. The products of combustion, as well as those of stewing, go out at the back of the cell or furnace quite near the feed opening, and pass into the main flue without being brought over the hotter part of the hearth, where the red-hot cinder lies. In the re-charging of each cell with more refuse, the stuff again falls on the dead hearth, and, whilst there, the drying and stewing vapours are at once carried out by the back into the main flue, and are not brought over the hotter part of the cell or furnace. It follows, therefore, that there is ample opportunity afforded for imperfectly consumed gases to escape unburned into the main flue, from which, unless the temperature there is very high, they must escape to the chimney and hence into the atmosphere of the neighbourhood. My observations on the Fryer's destructors in actual operation have not led me to the conclusion that, under ordinary care and attention, they can be worked satisfactorily. Indeed, at only one station, viz., at Whitechapel in London, did I see this destructor fulfilling all the conditions of a destructor, and the success there was mainly due to the apparatus being under the constant charge of skilled stokers and under high-class supervision.

In the Fryer's destructor proper, the supply of air to the cells or furnaces is entirely determined by the draught in the chimney stalk necessarily causing a suction of the air through the burning refuse matter. There is no forced draught of any kind under the fire-bars, and the ashpits are quite open. The general result of working this destructor, therefore, is that the heats are not sufficient for fully dealing with the combustion of the refuse. There is a tendency for foul-smelling gases to pass away unconsumed; for the cinder stage to be only a dull red-heat, and for the clinkering of the residue to be imperfect. I have seen the stuff dragged out of this destructor in an inflaming condition, and the cinder and clinker still glowing and burning, and evolving organic and sulphur gases most abundantly, rendering the atmosphere quite suffocating and nauseous, whilst the fine dust was being blown about all around and over into neighbouring properties.

The imperfectly burned gases leaving the Fryer's cell, and going by the main flue to the chimney, are supposed to be consumed in the main flue, but unless the temperature there is a full red heat, about 1,500° F., these gases cannot

be properly burned there. As I have often seen the main flue at a black-red heat, not above $1,000^{\circ}\text{F.}$, it was impossible that the organic gases could be rendered innocuous. The deficiency has apparently been admitted at several stations by the construction in the main flue, between the cells and the chimney, of a cremator where coke is being burned, and the gases travel over the bed of red-hot coke, and are there consumed. In this way the admittedly imperfect combustion of the refuse products in the cells is met by the use of a cremator, which requires extra labour, and involves additional cost in fuel.

In the Horsfall destructor, Fig. 2, there are two important

Fig. 2.

A, Hopper feeder, generally dispensed with; B, fire-bar grating; C, escape service flue at front; D, ashpit; E, steam air-blast; and F, main flue to chimney.

improvements, and both conducing to more perfect combustion. First, whilst the cells are fed from behind, the escaping gases and vapours pass away from the cells near the front of the furnace; and second, that a steam-air blast is introduced below the fire-grate in a closed ashpit, which admits of a forced air draught being sent through the burning refuse.

The first of these improvements is carried out by providing a number of openings in the side wall and roof near the front of each cell, which communicate directly with a branch or service flue leading to the main flue, and through which all the burned gases and escaping vapours must leave the cell, and ultimately pass to the chimney stalk. As each cell is fed from behind, either by a hopper, or as generally practised, through a back-feed opening, it necessarily follows that any stewing process which may occur when the refuse is freshly thrown in, takes place at the back of the furnace, away from the outlet flue, and that vapours produced at the back of the hearth must pass over the whole bed of material lying on the hearth before they escape at the front part of the cell.

In principle, therefore, the Horsfall destructor cell should do the work of more fully burning the refuse gases than in cells where the feeding of the refuse and the escaping gases and vapours take place at the same end of the cell; but for practical working, and having regard to the raking forward of the fresh refuse over the whole available hearth, it does follow that there is too little glowing hearth over which the organic smelling vapours are compelled to pass, to admit of the regular and efficient raising in temperature and combustion of the whole into non-smelling and innocuous gases.

The second improvement, consisting of the steam-air blast, is not only of great service in admitting of a full draught of air permeating the fire-bars and quickly raising the temperature of the refuse debris on the fire-bar grating beyond what is possible by mere chimney-draught; but, in addition thereto, the steam, in passing through the glowing carbonaceous cinders, becomes broken up and yields two highly combustible gases, viz., hydrogen and carbonic oxide, and such being afterwards burned in the atmosphere of the cells and in the service and main flues, most materially assist in raising the temperature and in consuming the noxious-smelling gases evolved from the fresh or non-charred town refuse, and aiding in these being changed into innocuous and non-smelling gases.

Difficulties, however, do arise in working the Horsfall destructor, owing to the closing up of the comparatively small escape openings leading into the escape service flue, which is due to partial fusion of the brickwork at the high temperature and the adhesion of dust particles to the sides of the openings. The result is the reduction of the openings and draught, and the lessening of the power of the destructor, until the apparatus has been thrown out of work for repairs. Even when working properly, each cell is independent of every other cell, and if any heavy charge of green stuff be thrown in, the temperature of the cell may become materially lowered, so as to admit of foul-smelling gases passing away unconsumed for a time.

The Bradford and Leeds destructors were originally Fryer's, but they did not work satisfactorily. The temperature obtained by the chimney draught was too low for the proper combustion of the smelling gases, either in the cells or in the main flues. The results were that complaints were made of the existence of a nuisance. At both places, alterations were made in the destructor by closing in the ashpit and admitting the air by steam air-blasts into the closed ashpit, and thence by forced draught through the fire-bars and refuse burning thereon.

This improvement at once brought up the temperature in the flues from a barely visible red, about $1,000^{\circ}\text{F.}$, which it was previously, to a cherry-red heat, $1,500^{\circ}$ to $1,600^{\circ}\text{F.}$, and even higher. I have personally seen the pyrometer showing fully $1,500^{\circ}\text{F.}$ in the main flues in these destructors. These results proved conclusively the advantage of the steam air-blast for raising the destructor cells to a proper heat for consuming the refuse and burning the smelling vapours into innocuous gases. After the use of the steam air-blast in closed ashpit, the complaints as to a nuisance ceased. The clinker is now also properly burned, and forms an innocuous fused residue incapable of evolving any noxious gases.

At Leeds, Mr. Hewson, the borough engineer, made further improvements by constructing a new furnace, Fig. 3, where the

Fig. 3.

A and A A, feed-holes; B, dead hearth; C, fire-bar grating; D, exit service flue at front; E, ashpit; F, steam air-blast; and G, main flue to chimney.

outlet flue from the cell passed away from near the front of the cell; so that, whilst the feeding was at the back, the escape of fumes was near the front, and the gases and vapours practically passed over the whole surface of the cell before they escaped to the flue and chimney. Still, as each cell continues to be worked by itself, the re-charging with town garbage must reduce the efficiency of the single cell to burn properly its own gases for a time, and during this period smelling gases must tend to escape to the flues, and thence by the chimney to the atmosphere.

At Warrington, the Beaman and Deas' destructor is being worked, as also a converted Fryer destructor. The latter has been improved by closing in the ashpit and admitting a blast of air driven by fanners. The result has been much increase of heat and better combustion. Still, the feed opening and the flue escape are at the back of the cell alongside of each other, and the smelling gases

are not brought over even the single glowing hearth when it is in proper heat.

The Beaman and Deus' destructor proper, Fig. 4, consists

Fig. 4.

A Feeding inclined plane; B fire-bar grating; C main flue to boilers or chimney; and D ash-pit with fan air-blast.

of a cell which is fed at the one side and the escaping gases pass away from the opposite side of the cell into a main flue. The hearth is 5 feet by 5 feet, and there is no dead plate. The fire-bars are very close to each other, and little dust passes through. The ash-pit is closed, and a blast of air driven by fans enters the pit and flows through the furnace bars and thence through the refuse fuel. From actual observation, I know that the temperature obtained is very high—probably 2,000° F. in the main flue,—and there is little chance of any smelling gases escaping. With careful stoking the vapours have always some red-hot surface to pass over, and the temperature in the main flue is sufficient to cause their combustion into innocuous gases. It would only be when the cell was heavily charged with fresh refuse, and the temperature lowered for the time, that anything could escape destruction.

The Meldrum destructor, Fig. 5, differs materially from

Fig. 5.

A A A A Four cell grate furnaces; B B B B dead plates between the cell grates; C fire bridge; and D main flue to boilers and chimney.

any of the preceding destructors in arrangement, for several of the grates—say four—are placed side by side, and separated only by dead plates, so that the various cell gratings virtually form a quadruple combination hearth. As each cell grate has an independent ash-pit, which is closed in and fed with air under pressure, preferably by steam air-blast, it follows that the several grates can be worked separately or in combination as desired. Whilst at full work the destructor is practically a single cell which may be fed and clinkered off at four places at regular intervals, and thus a somewhat constant temperature of the whole may be looked for. The escape gases may be passed away from the back of each fire-grate into a common flue leading to boilers or the chimney, or they may be transmitted sideways over the various grates and thence over a common fire-bridge in the direction of the boilers or chimney. My inspection of this destructor at full work satisfied me that an excellent temperature could be got up and maintained in the various grates when all the doors were closed, but the mode of charging the respective grates by hand feeding, with the doors open, led to the entrance of much air into the combination, which must necessarily have a cooling influence on

the whole, and lessen the efficiency of this destructor for consuming the smelling gases evolved from the foul garbages, especially when the newly charged grate is near the chimney end of the combination.

Other destructors might also be referred to, but the essential points included in the less known constructions have been already mentioned in those forms of destructors which have been described.

The difficulties connected with destructors in general for the thorough combustion of the refuse and the escaping gases into innocuous matters, arise mainly from the varying condition of any single cell from time to time, so that, even when it is possible to get up the proper temperature when the cell is in full blast and in the cinder and clinkering stage, yet, when the charging operations are proceeding, and for some little time thereafter, the temperature becomes lowered below what is required for efficient treatment of the refuse and its products. To overcome the deficiencies, recourse has been had to the use of cremators, which practically form part of the main flue, and where a bed of red-hot coke or other fuel is supposed to be constantly burning, and over which the smelling gases must pass and ought to be consumed. The suggestion and construction of these cremators is an admission of the inefficiency of the destructor proper, and are a mere whitewashing of an imperfect machine. The cremators are costly in working, are not properly attended to, and though I have repeatedly looked at them during my inspection of the destructors, and have even been told beforehand that they were in operation, I have never yet found one of them in actual full work, though otherwise they were in serviceable condition. A cremator should not be called upon to check or rectify the imperfections of any destructor, and the destructor proper should be capable of doing its own work.

After full consideration of the efficiencies and deficiencies of the various forms of destructor presently in use in different parts of the kingdom, and a large number of which I have personally inspected, I have arrived at the conclusion that not one of them accomplishes, so satisfactorily as should be done, the thorough combustion of town refuse into innocuous matter—gaseous and solid—with that certainty which should remove the word nuisance from the operation.

There are good points in all the destructors, and I have endeavoured to take advantage of the better parts in each destructor, and put these together—so far as these are jointly workable—and have combined therewith an important additional improvement, by causing every set of two cells to work together by a duplex reversible action, which will ensure double efficiency in destroying the refuse and removing any cause of nuisance.

The fires in each single cell must always slacken or deaden down when a fresh charge is added to the cell, and in any case—even when well burning—there must always be a very limited space in each cell for the vapours produced within itself to come in contact with the red-hot glowing cinder within its own hearth, or even with the burning gases passing away from the single cell. Consequently, where only one cell of a destructor is worked independently of every other cell, so far as each cell and its contents are concerned, there must always be ready opportunities for the escape of improperly-burned vapours from the cell, but where two cells are so connected together, then the vapours coming from the one cell can be fully burned by passing over the second cell, and proper and efficient combustion can be insured.

I propose, therefore, that each two cells of a destructor shall work into each other's hands, and that where one of these cells shall be so far burned as to be all aglow and the hearth quite red-hot, the other of these cells shall be at the re-charging point, and that the green-smelling organic gases evolved from the latter shall be transmitted, by a side communicating flue, over the red-hot surface of the hearth of the former or glowing cell, and then this process shall be reversed, when the alternate cell shall come to be charged with fresh refuse.

The three conditions required for the proper working up of town refuse in any destructor can be most readily and

efficiently carried out by this duplex system. These three conditions are—

1st. That the inflaming part of the refuse, and the gases and vapours arising therefrom, shall be at once brought in contact with a surface of red-hot fuel, and be consumed into non-smelling and innocuous gases;

2nd. That thereafter a good, clear-burning cinder shall be obtained on the hearth, which will continue to burn and glow, whilst only emitting ordinary chimney gases; and

3rd. That finally a well-made clinker will be formed, practically free from carbon and sulphur, and non-smelling, which can be easily removed, and being devoid of combustible elements, will readily cool down like a bit of red-hot brick, and leave a dead clinker.

These three stages, viz., inflaming, cindering, and clinkering, will, in practical working, be carried on alternately in each of the two cells forming the duplex system; taking care always that the gases from the inflaming stage in the one cell are transmitted over the red-hot cinder stage in the other cell, and thence, when burned, passing into the flue leading to the chimney stalk.

Fig. 6.

Thus Fig. 6 is a front vertical section of the improved destructor representing the two cells A and B arranged to work into each other by the duplex system. Each is provided with an exit service flue at the back which can be opened or closed by a damper, and there is a flue connection between the two cells at C, near the front of the cells. Granting that cell B has passed into the cinder stage, and the whole hearth is red-hot and aglow, then cell A, which is also in fire, is charged with fresh refuse from the feeding-hole at the back, which is spread over the cell floor. The damper of A being closed, no partially consumed vapours can escape in this way, but the damper of B being open, all the smelling vapours from A must be carried by the flue C over the glowing cinders and burning gases in B, and after being consumed into non-smelling innocuous gases, will escape by the open service flue of B into the main flue, and thence into the chimney.

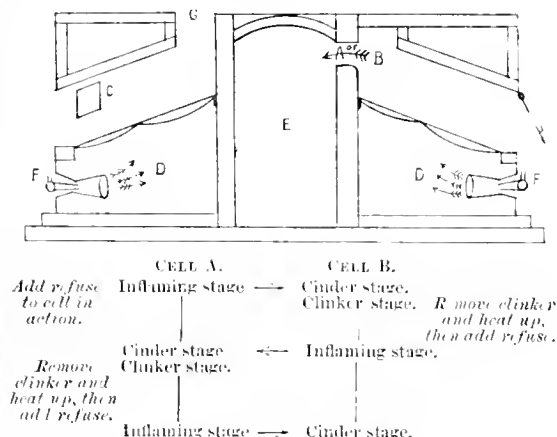

This operation will go on till the charge in A cell has become cindered, when the contents of B cell will be found to be more or less clinkered. The irons are then used in B cell to remove the masses of clinker to the surface of the ashes, and thence out of the cell to an iron barrow placed conveniently in front. Thereafter, the furnace door of B cell being closed to raise the temperature of the remaining cinder bed lying there, the current is reversed in the cells by opening the damper in cell A and closing the damper in cell B, and thus B cell becomes ready to receive the fresh charge of town refuse, the fumes from which will pass by the connecting flue C over the red-hot cinder bed of A, and after thorough combustion by the flue at A, to the main flue and chimney.

The general arrangements of the Duplex destructor may also be observed from Fig. 7, which is a transverse vertical section of the apparatus. A or B showing the position of the service flues of the coupled cells as entering the main flue, C is the connecting flue forming the communication between the two cells which are worked together, D is the

closed ashpit under the cell fire-bar gratings, E is the main flue leading to the chimney, F is the steam air-blast, and G is the feeding-hole for charging the cell with fresh garbage.

Probably the various stages in the working of the Duplex destructor may be more readily observed in the following statement, where the arrows represent the direction in which the vapours and combustion gases will travel in the cells on their way to the main flue and chimney.

Fig. 7.

And so on, repeating the operations, and reversing the flue currents, as each fresh charge of the town refuse is added alternately to either of the two cells working on this duplex system.

By this method of consuming the refuse, it is apparent that one of each two cells is always, when in the cinder and clinker stage, not only burning off its own material, but is also acting as a live cremator for the thorough heating and combustion of the noxious vapours and gases from its neighbour cell, and that good office it is fulfilling without any extra trouble than merely reversing the flue currents by alternately opening one damper and closing another, and at absolutely no cost for coke or any other sort of fuel, or even labour. Moreover, the beneficial operation is carried out in the immediate presence of and under the constant eye of the man responsible for the proper working or stoking of the respective cells, and the thorough combustion of the refuse.

The working of a large bench of such duplex cells would be quite as easy and would be more effective than by any other system. Thus a bench, say, of 12 cells, either in a single row, or, still better, divided into two rows of six each, placed back to back, and with the main flue between, would have the coupled or duplex cells arranged as follows:—

On the one side, cells 2, 4, and 6 would be in the cinder stage, and would have their service flue dampers open to the main flue, and the cells 1, 3, and 5 would be in the inflaming stage, and have their gases and vapours respectively carried through 2, 4, and 6 to the main flue and chimney; whilst on the other side 7, 9, and 11 would be in the glowing cinder stage and their dampers open and the inflaming, probably smelling, gases from 8, 10, and 12 would be passing over their glowing hearths. In this way no two immediately opposite cell service flues would ever be open at the same time for the escape of the burning gases to the main flue and chimney, and thus the reversing process considered so essential in this improved destructor would be still further carried out in the main flue.

The duplex cell system may be best worked out with the aid of a forced steam air-blast F directed into the closed ashpit D below the furnace bar-grating. A fan air-blast would be also serviceable in the same position. 1

am not, however, at all sanguine that mere chimney draught, which has practically failed in other destructors, could be depended upon for efficiency, even when aided by my new system. I am decidedly favourable to the steam air-blast—two steam jets with air-funnels being provided for each cell and entering the closed ashpit in front at the sides, leaving the centre of the ashpit door to be opened for removing the fine ashes which have passed through the fire-bars. The ordinary disposition of these arrangements, as indicated in Figs. 6 and 7, will be found serviceable. With the steam air-blast, one great advantage lies in the steam undergoing breaking up in contact with the red-hot carbonaceous cinder of the cell hearth, and yielding the combustible gases, carbonic oxide and hydrogen, so useful from their own combustion in materially raising the temperature of the cells and flues, and thus aiding in bringing about complete combustion of the noxious smelling gases evolved from the garbage.

One important part of any well contrived destructor is that there should be no dead hearth for the stewing of the refuse garbage. The whole bed of the cell or furnace should be a living fire-grate, through the bars of which air should permeate and assist in consuming the organic matter over the whole extent of the hearth. Such being the case, the actual fire hearth in the duplex cell may be enlarged so as to include part at least of the space taken up by the dead hearth in other destructors, and give a living fire-grate surface of at least 8 ft. by 5 ft. or 40 ft. of burning area, instead of 25 ft. as in most destructors. The enlarged fire hearth will necessarily increase the amount of refuse which can be efficiently dealt with in each cell, and at the same time ensure that the garbage is not stewed or smothered, during which period the most objectionable vapours and gases are disengaged.

The common way of charging the cells with fresh refuse is objectionable. The material is tipped down practically on the top of the cells, where it becomes heated and often fired, and offensive vapours are evolved. Even during the charging, the material is apt to be blown about while it is being shovelled into the feed-hole, and much dust is wafted away to the neighbourhood. I am strongly in favour of the waggon-charging system introduced by Burnos and Brodie at the destructor in Vauxhall Road, Liverpool. The waggon runs on rails, is divided into compartments, eight or so in number, and the carts conveying the refuse are tilted right into the waggon compartments. Each compartment contains a full charge for a destructor cell, and the waggon being run over the feed-hole of the cell, the cover of the cell and the bottom of the compartment of the waggon can be simultaneously opened, when the charge of refuse at once drops into the cell, and immediately thereafter the cell and compartment are again closed up. The whole operation is a question of seconds, and there is practically no dust evolved and no smell disengaged.

The question of the particular form of fire bars in a destructor does not, in my opinion, affect much the working of the destructor. I am rather favourable to stationary fire-bars with little space between each of the bars, so that as little fine matter as dust shall fall through into the ashpit. I believe more in effective clinkering for the removal of the ash matter in a semi-fused state, so that little actual dust need pass through between the fire-bars. In any case, when the ash pan door is open for the removal of its contents the dust should be well watered, if not already damp from condensed steam, before being shovelled out into a barrow, and the material should be buried, so as to keep it from being blown about after drying. The space between the fire-bars should be more regulated, so as to suit the influx of the air by the steam air-blast than for the removal of the fine dust from the fire grating of the cell; and what is sufficient for the supply of air for proper combustion will be ample for the dropping down of the necessary ash dust.

The question of dust nuisance arising from refuse destructors cannot be overlooked, as in many places it forms an undoubted nuisance and cause of complaint. It may arise from several causes:—

1st. From the raw green refuse being tilted down by the carts in positions where the wind can blow it about,

and by the ordinary shovel way of feeding the cells. Such can be obviated by paying proper attention to the reception yards being efficiently enclosed, and by using travelling waggons for charging the cells.

2nd. From the improper raking out of matter from the front of the cells either wholly or partially burned. This is a most unnecessary and improper procedure, and rendered doubly a nuisance when water is thrown on the rakings, which causes disruptive discharges in the hot material and a great increase in dust and smell. Such may be obviated by insisting on proper clinkering of the cell refuse and by the removal of nothing but clinker, thoroughly burned, and practically non-smelling, and which quickly cools down.

3rd. From excessive and unnecessary movements of the fire-bars, especially when rocking or oscillating bars are in use, and the ashpits are open to the air. Such can be obviated by having closed-in ashpits, and by drenching the ashes with water before removal.

4th. From excessive draught in the flues and chimney, when much dust and even half-consumed papers are swept onwards by the current, and are seen passing out at the chimney head, and thereafter fall down on neighbouring property. Such may be obviated by placing screens with $\frac{1}{2}$ -inch and $\frac{3}{4}$ -inch meshes in the main flue near to or at the bottom of the chimney, for the arrestment of the papers, and by admitting of the finer dust being deposited in properly constructed dust chambers. Attempts have been made to arrest the dust by placing balling walls, columns, or plates in the ordinary flues, but these are often restrictions in the area of the flue, and are of little use in arresting the dust, owing to the current or draught failing to be checked by such obstructions, which practically form restrictions in the area of the flue.

Dust chambers can be of little use unless the current of air or draught is temporarily lessened by expanding the main flue to several times its own area, or by causing the main flue to enter and leave a large dust chamber which is several times the area of the main flue. The current of air or draught in the main flue of a destructor may be as high as 20 to 40 miles an hour, and if the flue goes direct to the chimney without any expansion of its area, it is impossible that any large proportion of the dust escaping from the cells can be deposited in the flue and the chimney. But enlarge the area to double that of the main flue—or cause the main flue to enter and leave a dust chamber with twice its area—before it reaches the foot of the chimney, and the air current or draught will be reduced from 20 or 40 miles an hour to half the speed, viz., 10 or 20 miles an hour; and if the area of the main flue or dust chambers be quadrupled, then the speed of the air current or draught will fall to 5 or 10 miles an hour; and in either case, especially in the latter, much dust will cease to be carried forward, and will be deposited in the expanded flue or dust chamber. I am of opinion that every dust chamber should be at least four times the area of the main flue of the destructor, so that if the main flue is 10 ft. by 6 ft., or 60 ft. in area, the dust chamber should be at least 240 ft. by 12 ft., or 240 ft. in area. And if balling arrangements, such as walls, columns, or screens, are introduced, then further allowance must be made for the space occupied by these, so as to ensure that a free area of the full size and capacity shall be left for the due settlement of the dust, without its efficiency being neutralised by air currents and eddies circling round the balling arrangements.

The following statement may be taken as a summary of the main points and advantages of the duplex destructor:—

1st. That the three stages in the consumption of town refuse, viz., inflaming, cindering, and clinkering, are fully recognised as a working basis.

2nd. That each two cells of the destructor can work into each other, so that the green or smelling gases of the one cell are thoroughly consumed over the red-hot cinder-hearth of the other cell.

3rd. That the action of these cells is reversible by the mere act of opening and shutting dampers, and such constitutes a duplex reversible system.

4th. That the requisite temperature of the cells of the destructor is fully brought up and maintained by steam air

blast or fanner-air blast, introduced below the fire-bars. Preferably the steam-air blast.

5th. That the clinker is thoroughly burned out, and is alone removed from the cells, excepting the fine dust which passes through between the fire-bars into a closed ash-place.

6th. That the clinker so removed is practically free from carbon and sulphur, and may be allowed to deaden or cool down in the open air, without the addition of any water.

7th. That the contents of the closed ash-place, if not moist from condensed steam, are drenched with water before they are removed from the ashpit, and that thereafter they are buried to avoid unnecessary dust in the immediate locality.

8th. That the flue-gases, including dust, are passed through enlarged flues or dust chambers—at least four times the area of the main flue—so as to slacken the speed of the air currents or draughts, and admit of the deposition of the dust before the gases reach the chimney. That this deposited dust shall be periodically removed from the flues and be buried, so as to keep it from being blown about.

Keeping these conditions in view, I have no fear but that the combination of the duplex reversible cell, with the wagon feeding arrangement, steam-air blast in closed ashpit, and enlarged dust chambers, will ensure that the refuse of towns can be properly and efficiently consumed in the improved destructors without becoming a nuisance to the neighbourhood, and at the same time with manifest advantage to the community.

Whilst regarding it desirable that the duplex system of working destructor cells or furnaces should be carried out under all the conditions stated above, and in apparatus constructed on the general lines recommended in this paper, there can be no doubt that the system admits of application, to some extent, in the various forms of destructors presently in use in populous places, and that without much structural alteration. Thus, in the Fryer's destructor, where one of the main objections to its efficiency lies in the garbage being fed at the back, and the vapours being led away almost alongside the feeding-hole, giving rise to offensive gases escaping into the main flue, and thence, by the chimney stalk, to the surrounding atmosphere, the difficulty would be greatly met by working each two cells on the duplex system. For this purpose it would only be necessary that a communicating flue be cut out the division wall between the two cells, and near the front, as shown in Figs. 6 and 7, at C, and that dampers be provided in each cell, which can be opened and closed as required, and thus each two cells of the Fryer arrangement might be worked on the duplex system, and the smelling gases of one of the coupled cells be compelled to pass over the glowing hearth of the connecting cell. Of course, the forced steam air-draught or fanner air-draught, with closed in ashpit, ought to be used at the same time, so as to ensure proper temperatures and the thorough combustion of the refuse and of the gases evolved therefrom. The same arrangement of connecting each two cells of the Leeds destructor by a communicating flue, and the alternate opening and shutting of the respective dampers, would also materially add to their efficiency for completely consuming all offensive matters and gases. By this simple device of connecting each two cells in the Fryer's and Leeds destructors, and reversing the currents, each cell would alternately act as a cremator for the other cell practically coupled with it, and the working power of the destructors would be materially enhanced. At the same time, when new apparatus is being constructed, the full conditions of the duplex reversible system ought to be adhered to, so that the maximum benefit of the system may be ensured.

At first consideration of the duplex system, it might be supposed that the arrangement is too complicated to be carried out by an ordinary workman. In reality, however, the system does not introduce any difficulty in the working of an efficient destructor. The main points about any destructor must be thorough efficiency in the machine for dealing with the town refuse, and skilful men to work the machine. Ordinary labourers will not do for any destructor, you must have trained and intelligent stokers accustomed to furnace work, and who will take a pride in

manipulating a machine which can do its work well. Under these circumstances, a man will feel that he has some satisfaction in the discharge of his daily duties, and will not fail to get the most out of the destructor. There is really no more complication in working duplex reversible cells in the improved destructor than there is in the alternate firing of the furnaces of two boilers placed side by side with each other, and the intelligent stoking of which keeps down the disengagement of black smoke from the steam boiler chimney head. In the duplex destructor, the attendant will simply keep the two cells which communicate with each other at different stages of the same process, by alternate charging and working off the contents of the cells in a manner similar to that in which any intelligent stoker keeps up the fires under his steam boilers, by alternate coaling or firing of the different hearths so as to ensure proper combustion with a minimum escape of black smoke.

Destructor Smells and Dust.

In concluding this paper reference may be made to the nature of the evidence which can be led in cases of nuisance from the destructors, which may be due either to inefficiency of the apparatus employed or to want of skill in the working of the process.

The smells may arise :—(1st.) From the tipping or charging shed, where the materials are emptied out of the carts, and are often spread more or less over the tops of the furnaces, where they are subjected to much heat, and undergo a process of drying and stewing, with the result that vapours with a "singel-like destructor odour" are markedly observable, and which are distinctly noticeable in the atmosphere of the neighbourhood to the leeward of the destructor. In high winds, even semi-consumed dirty papers may be blown about and fall in neighbouring properties.

2nd. From the furnace vaults or drawing chambers where the material is dragged out or raked out of the cells in a more or less imperfectly burned state, with the result of the disengagement of volumes of vapours with the singel-like destructor odour, accompanied and succeeded by sulphurous anhydride, and in places where water is used for quenching the red-hot debris the sulphurous anhydride is succeeded by sulphuretted hydrogen. Placing oneself in the line or track of the wind, the respective smells may be clearly observable at a distance of hundreds of yards from the destructor. A hypothesis has been suggested that the sulphur compounds, viz., sulphurous anhydride and sulphuretted hydrogen may neutralise each other, but practically they cannot do so, as the first has the start of the second, and a gentle wind of the velocity of $3\frac{1}{2}$ miles an hour will sweep on the sulphurous anhydride at the rate of 5 ft. in the second, or 100 yards in a minute, and such column of polluted air containing sulphurous anhydride will precede a second column (when water has been added) where sulphuretted hydrogen is present, notwithstanding the difference in density or the respective rates of diffusion of the gases. The practical result therefore is that the two sulphur gases can be distinctly observed in the atmosphere of the neighbourhood, even by the sense of smell, and no doubt they exert their respective deleterious actions on plant life, and more or less affect the vitality of the shrubs and other vegetation.

3rd. From the chimney head due to the imperfect combustion of the organic matter and vapours in the cells and flues. No doubt a good height of chimney, 180 ft. or more, will tend to distribute the fumes more widely throughout the atmosphere, but in a badly constructed or worked destructor, where the temperature is too low for the perfect and complete combustion of the fumes, there will necessarily be evolved from the chimney head a decided fetid singel odour which may be shortly stated as "the destructor smell." The escape of such foul gases from the chimney head depends much on the temperature of the cells, service flues, and main flue. We cannot be satisfied with a temperature less than that of a cherry-red heat—1,500° to 1,600° F. in the flues—and even the higher temperature of a yellow-red or orange—about 2,000° F.—may be held to be advantageous. Anything like a black-red heat—about 1,000° F.—must be regarded as of little service for the complete combustion-destruction of organic-smelling gases.

The dusts must also be included as main factors in any nuisance from the operations of an inefficient or badly worked destructor. These dusts may arise (a) from the charging sheds where the town garbage is thrown down from the carts, (b) from the furnace vaults during the drawing or discharging of the cells, and (c) from the vaults where water is thrown upon the hot *débris*, either by buckets or fire hose. In the latter case the clouds of steam are accompanied by much fine dust in suspension.

As a preliminary to the investigation of the destructor dust and its identification from ordinary road dust, and even railway dust, when the destructor is placed in the immediate neighbourhood of railway lines, it is advisable to separate the coarser particles from the real fine dust, and that without any attempt to pulverise or reduce the larger pieces. This is most readily done by sifting the dust through sieves, and the trials made by me showed that a wire-gauze sieve with 1,600 meshes to the square inch—being 40 by 40—only kept back paper ash and lumps, small stones, cinders, &c., and the real dust which was liable to be blown about readily passed through the meshes. Indeed part of this fine dust would pass through a sieve with 6,000 meshes to the square inch. The proportions of 1,600 meshes to the square inch were found most suitable for working with all sorts of dust, whether destructor dust, road dust, railway dust, or field dust.

The identification of destructor dust may be carried out partly by chemical and partly by microscopic means. Firstly, it is found that when the dust is diffused through the atmosphere by sifting it through the fine sieve in front of the nose, the peculiar singed-like fetid odour characteristic of the destructor smell, is distinctly observed, exactly similar to that noticeable in the drawing vaults of the destructor. The same singed fetid odour is noticed on the person and clothes after each inspection of the apparatus, and when the mere running of the fingers through the hair, or the brushing or shaking of clothes, at once evolves sufficient dust to give rise to the peculiar characteristic odour. Secondly, when the dust is heated on platinum foil over a lamp, when the organic matter is burned away with the same destructor odour; and, thirdly, when some of the dust is added to water and the latter heated, when the steam evolved gives out a similar destructor smell.

Under the microscope and using powers of 70 to 140 diameters the destructor dust exhibits a marked lava-like or almost glassy structure of the fine particles, which is largely due to the disruptive action of the water thrown on the slaggy *débris* which had been withdrawn from the cells. The magnified particles are mainly jagged on the edges and very adherent, whilst here and there minute balls or bombs and the moulds from which these have been blown are observed. The same structure is seen when the dust is fully burned on platinum or when heated with nitric acid so as to destroy the organic matters, which leaves a residue markedly siliceous and glassy in texture and composition.

All of these general characters are observed in the dusts taken from the discharging vaults of a working destructor where water is thrown on the red-hot *débris* taken from the cells, as also from the dust collected from the outside yards and grounds, as well as from the fences and walls, as well as stems and leaves of plants, examined in the neighbourhood, and even on the scum taken from a sheet of water situated 100 yards from the destructor.

The facility with which wind will carry destructor dust is even greater than in the case of ordinary road dust, for whilst the latter has a specific gravity of 2.434 (water = 1.000) the destructor-gas has the specific gravity of 1.989, being a difference of 0.445 less density; and being therefore about 20 per cent. lighter than ordinary road dust, the destructor dust—equally fine in particles—is more readily lifted by winds and carried on in suspension. When deposited, however, as a layer on the leaves and stems of plants the destructor dust adheres more firmly to such owing to the jagged edges.

Ordinary road dust when diffused through the air by sifting through the fine sieve does not evolve any particular odour, and the same negative result is given when the road dust is heated with water. If placed on platinum and heated over a lamp the road dust merely evolves a slight

corky straw odour, and has no singed fetid smell. Under the microscope, the road dust is observed to consist of small stones, somewhat rounded and weathered, with only an occasional fragment of jagged glassy material.

Railway dust as taken from the permanent-way and from passenger platforms, when diffused through the atmosphere yields no particular odour; when boiled in water it emits a slight sulphury smell; and when heated on platinum foil it evolves a burned coal odour, without any singed fetid smell. Under the microscope, the fine particles are found to consist of minute cinders and minute stones—cinder- and stone dust—with few fragments of jagged glassy material. The same characteristics are observed with other railway dusts, such as those taken from the tops of railway tunnels, from the iossides (not floors) of railway carriages, and from railway waiting-rooms.

The quantitative analyses of the various dusts also bring out the difference between destructor dust on the one hand and ordinary road dust and railway dust on the other.

Thus destructor dust taken from the drawing vaults outside yards, and grounds, yielded

12 to 15 per cent. of organic matter and
50 to 55 per cent. of siliceous matter,

and destructor dust taken from the leaves of plants (principally laurels) growing in the neighbourhood of a destructor gave

15 per cent. of organic matter and
55 to 58 per cent. of siliceous matter,

whilst ordinary road dust yielded

2½ to 5 per cent. of organic matter and
80 per cent. of siliceous matter,

and railway dust from the permanent way gave

10 per cent. of organic matter and
fully 70 per cent. of siliceous matter.

The detailed analyses of many samples of all these kinds of dusts, as specially determined in a recent destructor inquiry, are given in tables A, B, C, and D on page 168.

SESSION 1895-96.

April 15th.—Mr. John White, F.I.C. "Filtration and Domestic Filters."

May 6th.—Mr. L. Archbutt, F.I.C. "An Evaporation Test for Cylinder Oils."

Meeting held Wednesday, March 4th, 1896.

MR. F. J. R. CARULLA IN THE CHAIR.

A paper by Mr. L. Archbutt on "An Evaporation Test for Cylinder Oils" was down for reading, but was unavoidably postponed until the May meeting.

THE ESTIMATION OF OXYGEN BY ALKALINE SOLUTION OF PYROGALLOL.

BY PROF. FRANK CLOWES, DSC.

THE author stated that it frequently happened in his laboratory that carbonic oxide was found in the residual gas from Brin's oxygen, after the oxygen had been absorbed by alkaline pyrogallol solution.

Check experiments, made by passing the oxygen over red-hot copper oxide, proved that no carbon dioxide was produced in this process, and that carbonic oxide was not, therefore, present in the original oxygen.

The alkaline pyrogallol solution used for the absorption contained 10 grms. of pyrogallol and 24 grms. of potassium hydrate in 100 c.c. This solution had been repeatedly used for the absorption of oxygen from atmospheric air, and it had always given perfectly satisfactory results, no carbonic oxide being evolved in the process.

Some experiments made with the above pyrogallol solution showed that it began to evolve carbonic oxide when the percentage of free oxygen present in the gaseous mixture exceeded 28. When a less percentage of oxygen than this was present, as is the case in atmospheric air, no carbonic oxide was evolved. When the proportion of oxygen in the mixture was made to gradually increase beyond 28 per cent. the volume of carbonic oxide kept increasing, until when the oxygen reached over 90 per cent. of the gaseous mixture, the volume of carbonic oxide evolved during the absorption reached 6 per cent. of the volume of oxygen absorbed.

It was found that if the absorption of the oxygen was followed by the absorption of the carbonic oxide by means of cuprous chloride solution, a perfectly accurate estimation of oxygen was obtained, presuming, of course, that no carbon monoxide was present in the original gaseous mixture. This was proved by estimating the percentage of oxygen in separate portions of one and the same mixture by means of the above pyrogallol solution followed by cuprous chloride solution, by absorption with phosphorus, and by firing with excess of hydrogen. The results obtained by the three methods were identical.

Experiments were then made in order to ascertain the effect of varying the proportion of pyrogallol to potassium hydrate in the solution. It was ascertained that if the proportion of potassium hydrate to pyrogallol was sufficiently increased no carbon monoxide was evolved during the absorption of oxygen, even when the oxygen was practically unmixed with other gases. A solution containing in 100 c.c. 10 grms. of pyrogallol and 120 grms. of potassium hydrate did not evolve any appreciable quantity of carbon monoxide during the absorption of oxygen under the ordinary laboratory conditions. The quantity of pyrogallol might be reduced in the above solution to 5 grms.

Prof. Ramsay finds that traces of carbon monoxide, which can be found spectroscopically, are always evolved during the absorption of oxygen by any alkaline pyrogallol solution. The amount evolved, however, when proper precaution is taken in preparing the solution is too small to affect the reading of the volume in a gas apparatus.

It will be evident from the results obtained by these experiments that serious error may be introduced into the estimation of oxygen by pyrogallol solution, unless the solution is prepared in such a way as to contain a sufficient excess of the caustic alkali. In the account given of this determination, it is not uncommon to omit all directions for the preparation of the pyrogallol solution, and it would therefore be naturally inferred that the composition of the absorbent solution is without influence upon the result of the absorption.

In the course of the investigation it was found that an alkaline solution of hydroquinone absorbs oxygen from a gaseous mixture, slowly but completely, and without evolving any carbon monoxide. The absorption is known to be complete when the absorbent solution, after having been shaken up against the interior of the vessel, flows down without producing a blue film. The similar absence of a brown film during the absorption by alkaline pyrogallol is usually accepted as an indication that the

absorption of oxygen is complete. The solution of hydroquinone used for the absorption of oxygen contained 18 grms. of hydroquinone and 24 grms. of potassium hydrate in 100 c.c.

The author expressed his acknowledgment to Percy Jackson for carrying out the experimental work involved in the above research.

DISCUSSION.

MR. JACKSON remarked that the absorption of oxygen by phosphorus was not always successful. It failed when certain hydrocarbon gases and vapours were present in the air, or when the proportion of oxygen was large, but when the phosphorus did absorb the oxygen, the absorption was rapid and complete.

THE CHAIRMAN said that he was pleased to infer from what had been said by Dr. Clowes that the error due to improperly prepared alkaline pyrogallate solution was not present in the test of the exit gases from sulphuric acid chambers, since oxygen was present in too small proportion to cause evolution of carbonic oxide.

MR. WARD supposed that the absence of CO in the original sample of gas was an essential requisite of accuracy in the experiments which had been detailed, in which the carbonic oxide produced during absorption with pyrogallate was subsequently absorbed and allowed for.

DR. CLOWES replied that no CO must be present originally, else the results would be erroneous.

MR. CAVEN made a reference to the possible presence of CO in the gases produced during the organic combustion of water residues by the Frankland process. Such CO would be calculated as nitrogen, and would seriously affect the determination of nitrogen in the organic matter.

DR. CLOWES: The error would be very serious with improperly prepared pyrogallate solution, and unless the analyst was satisfied that this error was impossible under the circumstances of the absorption, it would certainly be wise to make a final absorption with cuprous chloride solution before finally reading the volume of the residual nitrogen.

SOME PROPERTIES OF FERRIC PHOSPHATE.

BY R. M. CAVEN.

(*This Journal*, 1896, 17.)

DISCUSSION.

DR. CLOWES acknowledged indebtedness for a considerable amount of original work which Mr. Caven in his modesty did not claim. He thought confusion might arise in the minds of some readers of the paper by the phosphate radicle being sometimes called phosphoric acid; it might have been better if the expression "phosphate radicle" had been used throughout. He regarded the absence of colour in the first experiment made with HCl as conclusive that there was no FeCl_3 present, and he considered that this view met with further support from the fact that a solution of this salt gains in colour as it becomes more neutral. The paper will have some influence on our present analytical phosphate table, which will certainly have to be modified and, probably, simplified. The instance of hydrolysis of ferric salt given by Mr. Caven was not an isolated one, since ferric acetate solution undergoes a similar decomposition with the formation of a basic salt. Mr. Caven had only trodden on the fringe of the subject, and he (Dr. Clowes) hoped the author might find time to continue his investigations.

MR. I. J. PENTECOST remarked that ferric sulphate used by dyers under the name of "iron liquor or nitrate of iron" also underwent a decomposition on dilution with water, similar to that which had been described, and he believed that in mordanting with this substance some ferric hydrate was fixed on the fibre.

A solution of ferric pyrophosphate in ammonia had been used to a small extent as a cotton mordant.

MR. WILKINSON described an anomalous case in which when working with a solution consisting of a salt of zinc and sodium phosphate, on adding NH_4HO after NH_4Cl the zinc phosphate did not come down at all. He would like to know whether Mr. Caven could offer any explanation.

Mr. FORTH said that he found great difficulty in getting pure phosphates. When washing with water the impurities present might affect the result. He would like to know whether Mr. Caven had worked with the pure or with the commercial salt.

Dr. J. J. SUDBOROUGH considered the example mentioned by Mr. Pentecost as hardly a parallel one with the others in which hydrolysis occurred. The presence of the various organic substances acid and basic of the fibres upon which the ferric hydrate was deposited greatly altered the conditions of the case.

He also suggested that the colour of the residue after boiling FePO_4 with water or NH_4HO solution, might be an indication whether it consisted of a definite basic salt or of a mixture of FePO_4 and $\text{Fe}(\text{OH})_3$.

Mr. J. GOLDING pointed out the great interest that was attached to Mr. Caven's paper from an agricultural chemist's point of view.

He cited the method generally employed for the determination of the insoluble phosphates in acid manures by the precipitation from the hydrochloric acid solution of tribasic phosphate of lime by the addition of ammonia in slight excess, and mentioned a case in which he had had to abandon this method, owing to the presence of an appreciable quantity of iron, which, as Mr. Caven had shown, would vitiate the result of the determination.

Mr. CAVEN, in replying to the discussion, said that in the case of zinc salts, the precipitate formed on neutralizing a solution in which PO_4 was present, would be redissolved on adding excess of NH_4HO , since zinc phosphate is soluble in this reagent. The zinc could therefore be precipitated by ammonium sulphide in the usual way without the previous elimination of the PO_4 .

In reply to Dr. Sudborough he said that on boiling FePO_4 with NH_4HO , the salt quickly changed in appearance and, if granular, became coated with a dark red substance which appeared to be $\text{Fe}(\text{OH})_3$. He was of opinion that the fact of the gradual removal of the PO_4 , and also the appearance of the product, showed the improbability of a definite basic salt being formed at any stage of the operation. The change on treatment with hot water was so slight that no alteration in colour was noticed until after gentle ignition, when the mass appeared darker than unwashed FePO_4 .

In concluding, Mr. Caven thought that the phosphate table likely to be of most use for general qualitative analysis, would be one in which concise directions are given for the speedy removal of all the PO_4 as a phosphate of known composition, in such a manner that the course of the analysis can be quickly proceeded with in the ordinary way.

is often a matter of some difficulty when two or more of these bodies are present in a mixture.

We have sought in the classical archives of chemistry for reliable methods, and although we have found some of a fragmentary character yet their application has resulted in dissatisfaction.

A study of the modes of manufacture of the various thionates will reveal the fact that it is very easy to produce one or more of these compounds in our attempts to analyse mixtures of the materials from which they may be made. By the interaction of sulphuretted hydrogen upon sulphurous acid, pentathionic acid and the other compounds which characterise "Wackenroder's solution" (Debus, C. J., *Ann.*, 278, &c.) may be obtained.

By the digestion of sulphur with an acid sulphite, or, what is the same, by the heating of a solution of a thiosulphate with a mineral acid, trithionates are formed.

These facts dawn with unpleasant effect upon the minds of those who attempt to analyse complex mixtures of the radicals referred to, using methods which are presumably standard. Should the salt or solution be alkaline, one is advised to neutralise—with the sure result of liberating sulphuretted hydrogen, and, if a sulphite be present, also sulphurous acid—gases which in mutual reaction produce one or more of the thionates.

If the sulphates are to be determined we are advised to boil with oxygen-free water and hydrochloric acid in an oxygen-free space—presumably to prevent the oxidation of sulphurous acid; but if a thiosulphate is present sulphuric acid in no mean proportion is sure to be formed, and the accuracy of the estimation is entirely vitiated. There can be no doubt that thiosulphates when boiled with dilute mineral acids are partly converted into trithionic acid, which in its turn is decomposed, with the formation of free sulphur, sulphurous acid, and sulphuric acid:—

It is somewhat remarkable that thiosulphate of soda gives more sulphate when boiled with dilute hydrochloric acid in an oxygen-free space than when boiled in the open; but we have repeatedly proved this to be the case; in the open this salt has given us $2\frac{1}{2}$ per cent. of Na_2SO_4 ; in oxygen-free space it has yielded as much as $4\frac{1}{2}$ per cent. of this body.

There can be no doubt that the sulphate is due to an intermediary formation of trithionic acid; as by iodimetric titration the thiosulphate gave us 100 per cent. of $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{Aq}$; no sulphates were present, and none were formed by interaction with $\frac{N}{10}$ iodine (absence of sulphites); other tests showed the entire absence of dithionates, trithionates, tetrathionates, and pentathionates.

In order to accomplish—

(1.) *The Estimation of Sulphates in Presence of Thiosulphates, &c.*—None of the methods in vogue were of any value, and it was only after repeated failures that we worked out a completely satisfactory process to accomplish this object.

Hydrochloric acid speedily decomposes thiosulphate solutions, even in the cold, and sulphates are formed; acetic and oxalic acids have a similar result, and citric acid gives with barium chloride a precipitate which is too finely divided to admit of filtration within any reasonable period. Although barium chloride gives no precipitate with even moderately strong solutions of the alkaline thiosulphates, yet as soon as a sulphate is thrown down in the presence of a thiosulphate a very large proportion of barium thiosulphate will be found in the precipitate.

We find that an excellent result may be obtained by adding a solution of 5 gms. of tartaric acid to the solution, which is then precipitated by barium chloride in the cold; the precipitate can be readily filtered off, and the thiosulphates are kept in solution without suffering decomposition.

Some sulphite of barium remains in the precipitate on the filter, but this can be completely and safely removed by finally washing with hot dilute hydrochloric acid and boiling water.

SULPHIDES, SULPHITES, THIOSULPHATES, AND SULPHATES: THEIR ESTIMATION IN PRESENCE OF EACH OTHER.

BY F. W. RICHARDSON, F.C.S., ETC., AND H. E. AYKROYD.
ALTHOUGH it is not a difficult task to estimate any one alone of the radicals referred to in the title of this paper, it

The results obtainable by this method will be submitted for comparison towards the sequel.

2. *The Estimation of Sulphides* can be readily made by means of a standard ammoniacal zinc solution prepared according to Schwarz's method (see Sutton's Volumetric Analysis), and of such strength that 1 c.c. = 0.0016 gm. S as sulphide.

Our experiments were tried solely with the simple sulphides, but it would not have been a very difficult matter to determine the amount of "polysulphides" present, as these would be precipitated as polysulphide of zinc, the sulphur content of which would represent the character and quantity of the polysulphides to be determined. Nickel sulphate was used as the indicator, and was found to give excellent results.

To remove sulphides from the solution prior to examination for sulphites, thiosulphates, and sulphates, a slight excess of the ammonia zinc chloride was added, and the mixture was filtered. By our process this method appears to be wholly free from objections.

3. *Estimation of Sulphites and Thiosulphates*.—If one attempts to estimate sulphite of soda alone by the titration of its aqueous solution with decinormal iodine perplexing results are sure to be obtained, and we find that the use of oxygen-free water does not add much to the simplification of the problem.

Degree of dilution and temperature have much to do with the differences obtained, but degree of neutrality is even of greater import; indeed, free sulphurous acid in even very dilute solutions gives very erratic figures when titrated with decinormal iodine. A solution of SO_2 which gave 56 per cent. of SO_2 by complete oxidation to sulphuric acid and subsequent estimation in the form of barium sulphate, furnished the following figures with 5 c.c. :—

Ordinary Water.	Oxygen-free Water.	N I.	SO_2
C.c.	C.c.	C.c.	Per Cent.
50	..	7.5	0.48
100	..	9.2	0.58
200	..	9.6	0.61
400	..	9.6	0.61
..	100	9.6	0.61

Giles and Shearer (this Journal, III., 197, and IV., 303) have shown that it is necessary to add the sulphite to excess of $\frac{N}{10}$ iodine if accurate results are to be obtained, and this is our uniform experience.

We believe we have found a process which enables us to determine sulphites, and even free sulphurous acid, readily and accurately, not only in a pure form but even when mixed with sulphides, thiosulphates, and sulphates.

It is well known that when iodine solutions react with solutions of neutral sulphides neutral sulphates, and an equivalent quantity of hydriodic acid are formed :—

Thus a neutral sulphite of soda solution was added to three respective 20.0 c.c. of iodine until the reaction was complete; to neutralise the resulting colourless solutions were required :—

Phenolphthalein as indicator,	19.8 c.c.
Methyl orange	20.0 c.c.
Litmus	20.2 c.c.

Therefore the result with methyl orange was theoretically accurate.

We find that the best plan is to reduce all sulphites to the condition of bisulphite—that is, to the state of hydrogen-sulphite of the base; this is necessary because a sulphite may be alkaline, or it may be exclusively acid; indeed, a so-called "pure sulphite of soda" gave us, with phenolphthalein as indicator (knowing that bicarbonates of the alkalis are neutral to phenolphthalein), as much as $\frac{1}{10}$ per cent. of sodium carbonate. Sodium-hydrogen-sulphite is quite neutral to methyl orange, and by titrating the solution of a neutral sulphite with decinormal sulphuric acid, using methyl orange, we arrive exactly at a point

when all the sulphite is converted into the acid sulphite. This did not dawn upon us until we had obtained a number of results which gave the sulphite just half as large again as it should have been. The reason for this is patent when we consider the reaction which takes place when an acid sulphite acts upon iodine—

Here we have a new factor, inasmuch as the titration with alkali and with methyl orange as indicator is concerned; although the acid sulphite of soda is neutral to methyl orange, the acid sulphate of soda is acid to the full and exact extent of its combining power.

Thus one molecule of sodium-hydrogen-sulphite, on titration with $\frac{N}{10}$ iodine, liberates acid equivalent to three molecules of sodium or potassium hydrate.

A solution containing 1.62 per cent. of $\text{Na}_2\text{SO}_3 \cdot 7\text{Aq}$ was titrated upon. Iodine solution equivalent to 9.5 c.c. $\frac{N}{10}$ I; 29.9 c.c. were required; the mixture required 14.6 c.c. of $\frac{N}{10}$ NaHO. Now 9.5 c.c. $\frac{N}{10}$ I and 14.6 c.c. $\frac{N}{10}$ NaHO are in the ratio of 2 : 3 almost exactly; by using 0.0126 as the factor for the c.c. of $\frac{N}{10}$ I and 0.084 for the $\frac{N}{10}$ NaHO, both results give 1.64 per cent. of $\text{Na}_2\text{SO}_3 \cdot 7\text{Aq}$. (Of course the sulphite solution had been previously titrated with $\frac{N}{10}$ H_2SO_4 in the presence of methyl orange.)

As the details of calculation may be somewhat obscure to those who have not experimented in this direction, the working out of an actual analysis may be of interest. A solution containing 1.00 per cent. of pure thiosulphate of soda and 0.78 per cent. of sodium sulphite was titrated upon 20 c.c. of iodine; 19.3 c.c. were required to decolorise; to neutralise with methyl orange as indicator 17.9 c.c. were required; therefore 100 c.c. of the mixture required 103.6 c.c. iodine and 92.7 c.c. of $\frac{N}{10}$ soda respectively; the c.c. of soda $\times 0.0684$ give 0.7787 as the percentage of $\text{Na}_2\text{SO}_3 \cdot 7\text{Aq}$, and this figure $\div 0.0126$ (the factor for 1 c.c. iodine in $\text{Na}_2\text{SO}_3 \cdot 7\text{Aq}$) gives 61.8 c.c., and this subtracted from 103.6 c.c. of total iodine required gives 41.8 c.c., and this $\times 0.0248$ gives 1.036 instead of 1.00 per cent. of $\text{Na}_2\text{SO}_3 \cdot 5\text{Aq}$.

The immense advantage of this method is better seen in the case of a complex mixture, where one must remove sulphides or other bodies by the addition of an alkaline solution of zinc or other precipitating agent. The alkaline filtrate is speedily brought into a suitable condition for iodimetric and alkalimetric titration by the method proposed.

As a test case we give the following :—A solution of known amounts of thiosulphate of soda and sulphite of soda was treated with 10 c.c. of a strongly ammoniacal zinc-chloride solution, and the mixture was titrated with it until it gave a neutral reaction with methyl orange; it was now made to 1,000 c.c., and it was titrated upon a known volume of $\frac{N}{10}$ iodine, using starch to find the end reaction (which is otherwise somewhat obscured by the methyl orange). The disappearance of the blue colour and the appearance of the pinkish-purple of the acidified methyl orange is both interesting and striking. Titration with $\frac{N}{10}$ NaHO is now easily accomplished. The results were :—

	Present.	Found.
$\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{Aq}$	0.31	0.31
$\text{Na}_2\text{SO}_3 \cdot 7\text{Aq}$	0.29	0.22

A more rapid and satisfactory method it would be difficult to find.

We had previously tried Lunge and Smith's combined permanganate and $\frac{N}{10}$ iodine process for the estimation of sulphites and thiosulphates in the presence of each other, but found that the method was not only more tedious, but

that it was, in our hands at least, incapable of giving reliable results.

The following figures express a few of our results from the application of this process:—

---	Present.	Found.	Present.	Found.	Present.	Found.
$\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{Aq.}$	0.0583	0.0250	0.126	0.2058	0.126	0.2032
$\text{Na}_2\text{SO}_4 \cdot 7\text{Aq.}$	0.0254	0.0216	0.0209	0.0401	0.0209	0.0349

A far better method than this of Lunge and Smith (this Journal II., 463, and Sutton's Vol. Anal.) was arrived at ere the combined volumetric method above described was worked out.

After the sulphite and thiosulphate solution has been titrated upon a known volume of $\frac{N}{10}$ iodine, the sulphate formed is estimated by barium (any sulphate in the original solution is estimated by the tartaric acid method and deducted from the result), a little HCl being used in the boiling operation.

The results were on the whole very good.

We fully expected that the tetrathionate formed by the mutual reaction with the thiosulphate and the iodine would be decomposed in the boiling operation with the dilute HCl with the production of free sulphur and sulphate:—

But, strange to say, under the conditions of the analysis this never takes place.

True, we have obtained a very little BaSO_4 when thiosulphate was thus operated upon, but the amount has always been so small that it may have been easily due to a little impurity:—

(1.) 40 c.c. thiosulphate + 40 c.c. $\frac{N}{10}$ I thus gave 0.013 BaSO_4 .

(2.) 30 c.c. thiosulphate + 30 c.c. $\frac{N}{10}$ I thus gave 0.010 BaSO_4 .

(3.) 29.3 c.c. thiosulphate + 29.3 c.c. $\frac{N}{10}$ I thus gave 0.010 BaSO_4 .

These results were confirmed by many others, and we conclude that for every 10 c.c. of $\frac{N}{10}$ I in conjunction with 10 c.c. of $\frac{N}{10}$ thiosulphate, sulphate equal to 0.0025 gm. of BaSO_4 was produced. The following is an example of the application of our process to a mixture of known composition:—

	F.W.R. and H.E.A.		Lunge and Smith.
	Present.	Found.	Found.
$\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{Aq.}$	1.0000	1.0292	0.498
$\text{Na}_2\text{SO}_4 \cdot 7\text{Aq.}$	0.7800	0.7704	1.064
$\text{Na}_2\text{SO}_4 \cdot 10\text{Aq.}$	1.2220	1.2530	..
$\text{Na}_2\text{S.}$	0.0420	0.0430	..
	3.0440	3.0956	..

We have tried to estimate thiosulphate by boiling with dilute HCl in an oxygen-free space in connection with a condenser, carrying the distillation to dryness.

If this last condition is not carried out, only some 90 per cent. of the thiosulphate will be decomposed. Proceeding thus we have obtained from 1 gm. of thiosulphate 0.126 gm. sulphur (theory = 0.129); in distillate 0.248 gm. $\text{SO}_2 = 0.9612 \text{ Na}_2\text{S}_2\text{O}_3 \cdot 5\text{Aq.}$ Unfortunately very much depends upon the accurate estimation of the sulphur, which partly distils or is carried over by capillarity and is somewhat difficult to separate from the apparatus. As 1 part of sulphur represents nearly 8 parts of thiosulphate of soda, a little loss may mean a serious error in the results. It is none the less certain that such a determination serves as a

valuable check to the other data, and may be of utmost importance when we have to deal with mixtures containing thiosulphates and thionates.

G. E. Davis (this Journal, I., p. 88, &c.), in a paper containing excellent suggestions and also processes which in his hands at least appear to have given good results, makes use of strontium chloride for removing the SO_3 , and cadmium carbonate for removing the sulphide; but we find that these reagents do not satisfactorily accomplish the task assigned to them. Davis found that all titrations made of mixtures of sulphides and sulphites in presence of acetic acid, or of any acid which displaces sulphurous acid, are incorrect; this is also our experience, and we are glad to have found a method which renders any such combination of circumstances unnecessary; indeed we object to Davis's plan of adding acetic acid to the filtrate from the precipitation of the sulphide with zinc for iodimetric titration, as we have shown that thiosulphates are soon decomposed in the presence of this acid.

At an early date we are to read a paper upon the subject of "Cachou-de-Laval"; indeed, the processes we have just described lie at the very threshold of any investigation into the complex composition of this compound.

Our best thanks are due to Mr. Frank Wood, and also to Mr. Adolf Jaffé, for carrying out some of the experiments necessitated by this inquiry.

DISCUSSION.

Mr. F. W. RICHARDSON stated, in reply to an inquiry from the chair, that the sulphate was determined in a separate portion of the solution, and that excess of ammonium tartrate had to be avoided owing to its solvent action on barium sulphate. Tartaric acid by itself had been repeatedly proved to dissolve no barium sulphate—a crystallised sodium sulphate, tested thus in small quantities, giving over 99 per cent. of $\text{Na}_2\text{SO}_4 \cdot 10\text{Aq.}$

SESSION 1895-96.

April 7th.—Discussion on Mr. Stenart's paper, "The Standard of Minimum Flash-Point for Mineral Oil."

Meeting held in Glasgow on Tuesday, March 3rd, 1896.

DR. JOHN CLARK IN THE CHAIR.

THE STANDARD OF MINIMUM FLASH-POINT FOR MINERAL OIL.

BY D. R. STEUART.

1x November 1892, I read a paper before this Section on the flashing-point and heat of burning of mineral oils, and supplemented it, in December 1892, with a further paper at Edinburgh. In December 1893, some notes of mine were read at Manchester by Mr. Carter Bell. Many chemists

spoke in the discussions; and in both sections resolutions in favour of raising the standard to 100° were adopted. Strange to say, when Col. Majendie gave his evidence before the House of Commons Special Committee in 1894, he had never heard of these resolutions, nor of similar resolutions by the Chambers of Commerce of Manchester, Glasgow, Edinburgh, and Dundee.

I wish, in this paper, to recapitulate certain facts as to the relation between the Abel test and the point at which oil will explode in a lamp, or catch fire if spilled, and give new experiments; and in the light of present knowledge discuss how we and the Germans came to adopt such a low standard, and to compare that with the standards in America.

In the following experiments I tested the oil by trying to explode the mixture of air and vapour with spark from a pint bichrome battery and half-inch intensity coil. Explosive mixture, however, ignites more readily by the application of an ordinary light.

Exploding Oil at its Flash-Point.—I had an ordinary duplex lamp half filled with oil of 73° Abel test, heated for 1½ hours at 73°, and shook up gently before testing. The vapour flashed, blowing out the cork, with little report.

Dr. Thörner, of Osnabrück, with a very small lamp, 150 c.c. capacity and 100 c.c. of oil in it, of which 50 c.c. were drawn off before exploding, and trying, not to get point of severe explosion, but *lowest* point at which he could get explosion of any kind, found that the explosion took place sometimes a little under the flash-point Abel, but oftener a little above it. Of 30 experiments the average was 1·2 above the Abel flash-point, *two being violent*. With larger lamp, size of ordinary duplex, 800 c.c. capacity, 500 c.c. oil, and 100 c.c. drawn off, he found, average of four experiments each, with oil of 71·6° F. Abel, that the explosion took place at 72·5°, with oil of 82·4° Abel at 84·2°. *One explosion was severe*. So, as a demonstrated scientific fact, with some oils at any rate, *there is danger of severe explosion in a lamp even at its flash-point Abel*.

At a very few degrees above Abel flash-point, I often found explosion very severe. Oil of 792 sp. gr. and 80 flash-point, which was ordinary Royal Daylight petroleum, bought at random, heated in water-bath, reservoir of lamp 14,000 fl. gr. half-filled with oil, cork without hole, I got sharp explosions at 85°, 90°, 95°, and so on every 5°, up to 140°. All sharp explosions. We did not try higher temperature although the vapours had not got in excess. We heated in each case half an hour, beginning with oil cold. If we had heated longer, no doubt the vapours would have got in excess and ceased to be explosive. This shows that this kind of false safety can only be got by passing through point of severest explosion. Similar experiments with little hole in cork to let off pressure of vapour, heating 1½ hours at 120°, sharp explosion; 1½ hours at 140°, no explosion; with 3,500 fl. gr. oil, 1½ hours at 140°, no explosion; 1,000 fl. gr. oil, 1½ hours at 140°, no explosion. So, with longer heating the point beyond explosion from excess of vapour is got, if the temperature is high enough; but in these experiments the temperature required is far above the ordinary temperature of the common lamps of the people. So to trust for safety to excess of vapour is to deceive ourselves. Such safety, if safety it were, could only be depended on if oils were all guaranteed of low flash.

With an iron, single-burner lamp, fitted up with burner and ¾-in. wick, half-filled with oil of 73° flash, and heated 15° above the flash-point, the vapours exploded with violence, blowing the wick bodily out of the lamp some yards away. When heated 5° above flash-point, there was a flash or puff, not a sharp explosion, which blew the cork, which was not very tight, out. When tightly corked 5° above flash-point, there was no visible result. The oil for last two experiments had been used for several experiments and may have been somewhat exhausted of vapours.

The same lamp half-filled with fresh oil of 78° flash, heated 5° above flash-point, exploded violently, blowing out the cork, which was fixed in as firm as it could be

made, and at the same time blew the wick up three or four inches through the wick-tube. At 10°, 15°, and 20° above flash-point the results were similar; the explosions seemingly all alike severe.

I got oil reservoirs of tin made of definite sizes, and fitted with the Abel cap top, so as to test the flash-point in lamps of different sizes in comparison with the Abel flash-point.

Oil Flash Abel.	—	Different Experiments.
73°	Reservoir 2 ins. wide by 3 ins. deep, half-filled with oil.	Flashed at—69°, 70°
99°	Do. do. do.	98°, 102°
73°	Reservoir, 3 ins. wide by 3 ins. deep, half-filled with oil.	89°, 75°, 73°, 70°, 71°
99°	Do. do. do.	100°, 101°, 99°, 99°
122°	Do. do. do.	123°, 121½, 123°, 124°
78°	Reservoir 2 ins. wide by 4 ins. deep, half-filled with oil.	78°, 79°
78°	The same reservoir and oil filled to usual distance from top, 14 ins.	73°, 72°
99°	Reservoir 3 ins. wide by 2 ins. deep, half-filled.	95°, 96°
99°	Reservoir 3 ins. wide by 2 ins. deep, full to 14 ins. from top.	97°, 97°
99°	Reservoir 3 ins. wide by 4 ins. deep, half-filled.	93°, 94°
99°	Reservoir 3 ins. wide by 4 ins. deep, full to 14 ins. from top.	96°, 95°
78°	Reservoir 5 ins. wide by 4 ins. deep, half-full, gently shaken.	74°, 71°, large flash.
78°	Reservoir 5 ins. wide by 4 ins. deep, three-quarters full, gently shaken.	76°, 76° do.
99°	Reservoir 5 ins. wide by 4 ins. deep, full to 14 ins. from top, not shaken.	94°
73°	Do. do. do.	68°

So with ordinary lamps, the oil flashes under the Abel flash-point, and with large size of lamp, the oil flashes as much as 5° below the Abel test. When the reservoirs were tried half-full, as stated above, it was a little before the vapour mounted to the top of where the light was, but the flashes were very large, and the thermometer was suddenly sent up 2°. The reservoir 5 ins. by 4 ins., with top to fit the Abel top, had the Abel top removed, and the vessel with its 2-in. orifice used as an open tester. When full of oil of 73° Abel it flashed open at 72°; when half-full of oil at 71°; when full of oil of 99° Abel, it flashed open at 99°, and when half-full also at 99°. So for large lamp quantities of oil in certain circumstances the open flash-point is as low as or lower than the Abel flash-point.

Our opponents all dilate on the extreme fewness of lamp explosions, and put all the blame of lamps upset or broken on the lamps or the people. If a lamp is upset or broken with oil flashing above 100°, there are a thousand chances to one that the lamp goes out without doing harm. It may in the thousandth case cause a fire as any other light would; but the oil is not ignited at once; the burning wick would be some time on the pool of oil without igniting it, and if it ignited at all it would be slowly. Contrast this with a lamp with 73° oil upset or broken; the oil ignites so furiously that in common speech it is said to have exploded. Lamps upset are more numerous, no doubt, than explosions; but a lamp upset is perfectly innocent unless the flash is low. I see no need for the sharp discrimination of explosions and these sudden uncontrollable ignitions, for neither can take place except with dangerous low-flashing oil.

In Col. Majendie's 1890 report, Abel and Redwood gave details of 28 accidents happening between 30th July 1887 and 16th January 1890, and of these 23 were lamp explosions. In 1893, of the 36 accidents investigated by the London County Council officers, only 2 were acknowledged to be lamp explosions. How does it happen there were 82 per cent. of explosions in Abel and Redwood's cases, and only 6 per cent. in the London County Council inspectors' case? There was no change of oil or lamps in that time; but the facts as stated by the inspectors are influenced no doubt by their theoretical opinion that an explosion is nearly an impossibility.

With cheap lamps oil necessarily flows out when the lamps are overturned. Even if tight when new, they soon

get leaky, or else the burner is not screwed in tight. A safe oil makes any common lamp safe; but a good lamp cannot save accidents from low-flash oil. To depend on lamps, therefore, and designedly adopt oil of 73° on account of its giving off much vapour, and tends to become non-explosive, is a great mistake. The non-explosive condition, as I proved, is difficult to reach in practice often, and yet the oil, if set free, burns most fiercely. A year ago, through a friend in London, I got all the lamps then recommended by Mr. Spencer. Good new lamps, and carefully screwed home. On being lighted and overturned, all leaked, and, with one exception—a self-extinguisher—all took fire; and on attempting to extinguish the flame, one gave a serious explosion. The oil was ordinary American petroleum, 79° flash. In all cases, I tried to extinguish before the fire became so fierce as to spoil the lamps. The self-extinguishers cannot be depended on for continuous work unless in careful hands. I have known of several accidents with safety lamps. *There are few accidents with them, only because scarcely any are used.* Their safety depends on screws, and these soon get out of order, or are not screwed home, and then the safety lamp is an extra danger. Safety depends on safety tubes for the wicks, and these are a trouble in wicking the lamp, and will be left out without any thought of danger. Experiments with new lamps in good condition, like Mr. Spencer's, are worse than useless. Then the fount has to be of metal, and fount and safety tube cause heating of the oil, and increase the danger greatly, and entail many accidents that with glass would be free from danger. Safety lamps, to keep them safe, require intelligent treatment and care, and intelligence and care have to be provided against as necessarily absent; for it is only because they are necessarily absent that oil legislation is required at all. Metal lamps also tend to get filled too full, and when the heat comes with the burning, the expansion of the oil causes danger. To legislate as to lamps, and leave the oil of present standard, is necessarily to fail. I hear great things of new lamps Mr. Spencer has tried; but one thing is certain, that he cannot have discovered a lamp that makes the oil safe while still in barrels in the steamer, train, or shop, or in the oil-can in the house. Lamp legislation does not even attempt to cover one-hundredth of the danger of low-flash oil.

I tried the danger from upsetting cheap glass lamps, costing 9d. to 1s. each, flat-wicked single burners, half filled with the oil. I tried to get at the danger from burning, inherent in the oil itself, apart from the danger of over-setting on easily combustible materials—a danger common to all flames. After burning for some time, I tipped the lamp from the table on to an iron tray covered with broken bricks, so as to break it. The brick was to interpose a bad conductor between the oil and the iron, and prevent the oil being put out by the sudden chill from the cold iron. American petroleum, 73° flash, heated 5° above flash-point for half an hour, then tipped over: the lamp went out. Heated 10° above flash-point for half an hour: gave a flash, then went out. Heated 10° above flash-point for one hour: oil blazed up fiercely, no explosion. Heated 15° above flash-point for half an hour: oil caught fire, and continued to burn quietly; easily put out. Similar experiment with Russian petroleum of 87° flash-point, heated one hour 10° above flash-point: oil flashed, but went out. American petroleum of flash point 105°, heated 10° above flash-point: lamp did not break this time; some oil ran out, but lamp was only extinguished, and oil did not catch fire. Repeated the experiment: the lamp broke, but went out. Broxburn paraffin oil, 108° flash, heated 5° above flash-point for half an hour: went out. 10° above flash-point for one hour: oil gave a slight flash and went out. 15° above flash-point for half an hour: oil caught fire, burned two minutes, then went out of its own account.

Lamps at 9d. each smashed up wholesale soon come to money. I tried to gauge the same danger without breaking a lamp each experiment. I put a candle on the floor, covered with a hood to prevent the oil coming in contact with the flame, and I spilled quantities of oil equal to a lampful from a table on to the candle. If the oil caught fire readily, it must be from the vapours evolved. 100° flash-point oil, heated to 105°: light went out. Heated to

110°: did not catch fire, candle did not go out. Heated to 115°: oil caught fire, and burned very quietly. With oil of 73° flash, heated to 75°: much vapour rose from the oil, but it did not catch fire. Heated to 78°: did not catch fire. Heated to 83°: oil caught fire and burned quietly. Heated to 78°, and tipped over on to the floor while still hot from previous fire: the oil caught fire.

So high-flashing oils have very little danger in over-setting or breaking lamp, unless heated to, the altogether unusual temperatures of more than 10° above flash-point, while with ordinary low-flash oils danger begins 5° above flash-point, and therefore at ordinary temperatures of house and lamp. Any spraying of the oil by dashing on the floor, or from explosion of the lamp, will make the oil catch fire more readily. All these figures show that high-flashing oil is safer than low-flashing, even more than in proportion to the flash-point.

From these results we see that different oils of the same flash-point vary in their nature to some extent; and that for oil spilled by lamps over-setting, with oil of 73° serious danger begins at 78°, and with oil of 100° danger does not begin till 110° or 115°.

We come next to whether oils of 73°–85° or oils of 100°–120° develop most heat in burning. I have published several series of experiments on this point. One series of experiments gave a very slight increase with low-flashing oil over the temperature developed in the oil reservoir with high flashing, within the error of experiment almost, when the air-holes were quite clear; but when the air-holes were clogged, the temperatures with the low-flashing oils were distinctly the higher. In other experiments the general rule was an increase of heat with decrease of flash-point, although there were a few slight exceptions. In general, in my experience, the high-flashing oil, judging from temperature developed, is safer even, more than in proportion to the flash-point. I never in any case got with a high-flashing oil a temperature sufficient to neutralise its higher flash-point or anything approaching it. Abel and Redwood, in their 1890 Lamp Report, stated that "experiments have demonstrated that the burning of an oil of comparatively high flashing-point is *more likely* to cause heating of the lamp than the use of an oil of comparatively low flashing-point in consequence of the higher temperature developed by the former, and of the greater difficulty with which some oils of that description are conveyed to the flame of the wick." They did not say what temperature they found, and whether they ever got, *even in one case*, an increase of heat equivalent to the higher flash-point. They only gave the result as *more likely*, and built on it the warning that high flash-point was not alone to be trusted to, as "in certain cases such oils *may* give rise to dangers which are small, if not entirely absent, with oils of comparatively low flashing-point." They warn us, as it were, against the over-confidence in high flash-point; and they did not, as several thought, say that high-flashing oils were no safer than low-flashing ones and sometimes more dangerous.

The heat of burning developed in lamps is dependent on many little circumstances obscure to us. Atmospheric pressure and amount of vapour in the air probably tell on the result, and cause that one experiment is not exactly comparable with another. The amount of soda soap left in the oil by imperfect refining has great influence, and probably also the amount of sulphur in the oil. So that generalisations can only be made with confidence on the average of numerous experiments, or from samples carefully made comparable in manufacture. The German Government experiments found that lamps burned in cold chambers gave more heat than when burned in warm chambers, and the conclusion was that there was less heating in warm weather. The warm chamber was heated by many lamps being burned together in a small chamber, and the experiments continued for a fortnight, but this introduced unnatural circumstances quite different from plenty of warm summer air, and I would put the results aside as altogether worthless; as I know that what seems a very small matter sometimes has a great influence on the temperature developed. The interval between temperature of chamber and temperature of oil in reservoir is probably influenced by atmospheric temperature, but the same oil must

be tried in comparable natural circumstances. Scotch oil requires a little more air to burn it than American, and it is a matter of draught dependent on air-holes, chimney, &c., of lamp, whether the extra latent power in the oil appear in any particular case as extra white light with cool burner, or as extra heat with red light. So, oils of different nature, like American, Scotch, and Russian, cannot be properly compared by burning in the same lamp, as Mr. Spencer did. Each should have a lamp to suit it. In Scotland here, we probably have adopted types of lamps and chimneys to suit Scotch oil, while in London the lamps and chimneys, although to careless inspection the same,

may be expected to suit the American oil more. This may be the reason why I find the general rule to be that high-flash oil burns coolest, while Mr. Spencer is under the impression that it burns hottest. It may depend on a slight difference in length of Scottish and London chimneys to suit the prevailing oil, or something of that kind.

Instead of giving details of many experiments I will only give one. I took from a burning oil still samples at various points, so that all were comparable and each homogeneous in its nature, and tried the burning and took the temperatures after six hours.

Specific Gravity.	Flash.	Glass Lamp.				Metal Lamp.			
		Temperature			Increase of Oil over Room after 6 hours.	Temperature			Increase of Oil over Room after 6 hours.
		Of Burner.	Of Oil.	Of Room.		Of Burner.	Of Oil.	Of Room.	
790	118	104	57½	54½	3½	125½	66½	54½	12
805	165	100	55	52	3	131	67	52	15
820	205	96½	55	53	2	124½	68½	53	15½

The figures are in each case the *average* of three days' burning. With the glass lamps there is a gradual decrease of heat with increase of flash-point. With the iron lamp the results tend the other way; but the details of the different days differed much more than with glass. So that Mr. Spencer's working mostly with metal lamps may have helped to give him the impression that high-flash produces more heat. There is, however, nothing here to neutralise in the least degree the extra safety from the higher flash: only 4° difference of temperature for 87° difference of flash. With the metal lamps recommended by Mr. Spencer, I

found the Scotch high-flashing oil rather warmer than the low-flashing American petroleum, although nothing to neutralise the extra safety; but the lamps were no doubt adapted for petroleum and not Scotch oil.

Mr. Spencer, in his evidence before the Parliamentary Committee in 1894, gave figures which produced the impression that he had got more heat with the higher flashing oils, and talked as if this were a general law; and the committee in their conversation and questions took this law as granted. The figures he gave were as follows:—

	Scotch Oil, Flash 110°			Russian Oil, Flash 91			American Oil, Flash 82°		
	Temperature of Oil.		Increase of Temperature.	Temperature of Oil.		Increase of Temperature.	Temperature of Oil.		Increase of Temperature.
	On Lighting.	After 5 hours' Burning.		On Lighting.	After 5 hours' Burning.		On Lighting.	After 5 hours' Burning.	
1. Glass reservoir, without wick tube.	65	81	16	70	84	14	69	83	14
2. Metal reservoir, without wick tube.	65	87	22	70	92	22	69	89	20
3. Metal reservoir, with metal wick tube.	65	99	34	70	101	31	69	97	28

The temperature increase as given by Mr. Spencer was over the initial heat of the oil. Now that is a figure of no value nor interest. The oil soon warms up to the heat of the room from radiation, &c., and the room during the experiment may have been warmed from atmospheric influences or the fire more in one case than the other. The figures should have been, increase of temperature of oil at the end of experiment over the temperature of room at the end of the experiment. The figures then would have been—

Lamp.	Increase of Temperature of Oil over Room.		
	Scotch, 110 Flash.	Russian, 91 Flash.	American, 82 Flash.
1. Glass reservoir, no tube for wick.	6	6	8
2. Metal reservoir, no tube for wick.	12	14	14
3. Metal reservoir, with metal wick tube.	24	23	22

With both glass lamp and metal lamp without wick tube the Scotch oil with high flash developed even less heat than the American oil, and with metal lamp and metal wick tube

only 2° more. The Scotch oil was of 28° higher flash-point, and would have had to develop 28° of extra heat to have become as dangerous as the American oil. So even Mr. Spencer's own figures bear out the fact that there is no more heat with high-flash oil under ordinary circumstances in ordinary lamps.

As a matter of incontestable fact, then, the Abel flash-point may be reckoned the point of incipient danger for explosion in lamps, and at a very few degrees above it, varying with the nature of the oil, the explosion is or may be very severe. The larger the quantity of oil experimented with, the lower is the flashing-point. An oil which flashed at 78° F. Abel I tried in a 9-in. wide cup, covered over, and with circular holes to test by. I found the oil not only to flash, but to ignite permanently at 76° F., or 2° under the Abel test. In an open dish 9 in. wide, the oil permanently ignited at 87° F.

To test the danger of a large spill of oil on a floor, and the danger of a light applied to a large vessel of oil, I took a tray, 14 ins. by 10 ins., and put an inch of oil in it, and covered loosely with a sheet of tin. I put it in a larger tray of warm water, and heated the oil up slowly for 25 minutes. The flash-point (Abel) of the oil was 74½°, and when the temperature reached 79°—that is, 2° under the flash-point—the lid was lifted off and a light applied, and the oil took fire permanently. The firing-point of larger quantities of oil is the flash-point. I mean if the

vapour flashes it takes fire permanently. So the American firing-point is not the true firing-point, but sometimes 50° above it. For larger volumes of oil such as tin can, barrel, tank, or large spill on the floor, the firing-point is somewhat noder the Abel flash-point. This, at any rate, is the case with some oils.

I tested the diffusion of vapour into the air in this manner. I took a half-gallon tin can, shook up 4 oz. of shale naphtha, 730 sp. gr. in it, for five minutes, turned it upside down, and drained out with loosened cork, wiped the neck, and set it to stand on its bottom without a cork. I tried exploding after various intervals by pouring out the vapour on a lighted candle.

After 4 hours, very violent explosion.

" 6 "	" "
" 8 "	" "
" 10 "	not very violent explosion.
" 12 "	explosion still less violent.
" 14 "	very faint explosion.
" 15 "	no explosion.
" 16 "	" "

The Petroleum Committee of 1894 asked Col. Majendie, if he did not think 73° oil dangerous when the temperature of the air was above 73°. He answered that the close test was an artificial one, and that he did not think that with a barrel of oil of 73° flash and temperature 83° there was any danger of fire with bung half open. The open test is manifestly artificial and false, but the close test is an imitation of lamp and barrel on a very small scale, and therefore natural. I had not oil of 73°, but I tried a half-barrel of 82° flashing petroleum, heated to 92°, and drew off the mixture of air and vapour into bottles, and applied a light, and the bottles exploded readily. The vapour in the barrel was beyond the point of severest explosion from excess of vapour.

The Standard in America.—In Thorpe's Dictionary of Applied Chemistry, Mr. Boverton Redwood has the following remarks in an article on petroleum:—"The experience of many years has conclusively demonstrated that the transport and storage of kerosene of comparatively low flashing-point (say, 70° F., Abel test, or its equivalent), and its use in properly constructed lamps, is free from risk." The proportion of the total fires in London from petroleum, being over 19 per cent. of those of known origin in 1893, 23 per cent. in 1894, and 20 per cent. in 1895, after all the County Council's recommendation as to lamps, is a practical demonstration that the remark is contrary to fact and experience. He proceeds:—"This practical conclusion has been confirmed by recent experiments made in this country by Sir Frederick Abel and the writer, and in Germany by the officials of the Standard Office, and it has been found that some oils of high flashing-point may be actually less safe than others of low flashing-point. The tendency of modern legislation in the United States indicates a recognition of this fact." It would be a great pity if the legislation of a great nation like the United States, so much interested in petroleum, should recognise as fact such a tremendous error.

The Home Office, in the memorandum published on the Inflammable Liquids (1891) Bill, gave the flash-point of States and important cities in the States as they were some years ago, and Mr. Redwood gives in Thorpe's Dictionary, article petroleum, the more recent standards of the same places. I find that in five States, viz., Pennsylvania, Massachusetts, Vermont, New Jersey, and Minnesota, and also in the city of York itself, there has been a raising of the standard, and in not one case was there a lowering. The subject has been investigated by many State boards of health or other State official experts. Some States have no state law, but even of these some have efficient regulations and inspection in every town and village. Four or so have as low a standard as Britain, but these are producing States, and their low standard is used only for export. Order 73° oil from many refineries in Pennsylvania, and they would supply high-flash oil at a cheaper rate: they have no facilities for filling oil of low state standard in barrels; all that quality goes by pipe-line to New York. Some States have high standard but poor inspection; but many have high standard

and efficient inspection. There is a tendency to high standard and more efficient inspection everywhere.

The Standard in Germany by imperial statute is 21° C., or say, 70° F. But this is not recognised as a safety point. In this country cities or local authorities are by our imperial statutes prevented from taking any surveillance or precaution in regard to burning oil. In Germany the States and Cities were encouraged to regulate the oil trade, and did so. Shops are allowed to have 14 gallons of oil in stock, or 83 gallons with specified precautions; or if the shop is a dwelling-house, only 5½ gallons are allowed. This is the kind of trade we also will be obliged to adopt if we stick to our absurd standard. Germany has fewer accidents than England has, because Germany treats burning oil as we treat naphtha in law and in use, regarding it as a dangerous liquid.

It was shown to the German commission that England lost all its great Continental trade by raising the standard to 120° fire test (=73° Abel). The merchants argued quite rightly that 120° fire was practically no safer than 110°; that German ports and merchants had now 40 per cent. of the European trade; and that raising the standard even to the English standard would make them lose it all. This argument was conclusive. Prof. Hofmann, not knowing the question himself, was sure the English must have some reason for their standard, and made an appeal for 73° instead of 70°, but failed. He was in error. It would have lost their trade without gaining any safety. They were told, on Mr. Redwood's authority, that the English had made their standard so high for protection to the home manufacture. In their report they honestly state that the danger is in proportion to the lowness of the flash-point; that safety could only be attained by going far above 30° C. for standard; and they accepted the petroleum merchants' assertion that this would make oil too dear. They said: "The only question for us was whether oil of 23° C., as in England, or 21° should be adopted. This 2° was going to increase perceptibly the price of the oil, interfere with the German trade in foreign oils, and as proved by Dr. Weber's experiments, would have given practically no increased safety." So they conclude: "That with proper lamps, properly managed, at ordinary temperatures of the air, oil of 20° C. may be counted safe." They put it very carefully. They did not, as Mr. Redwood said, find 70° F. safe; but made the frank avowal that 70° oil was dangerous unless with special care and special lamps. So their conclusion was arrived at quite frankly in opposition to scientific requirements to conserve the Continental trade for German ports.

Legislation.—Paraffin oil from Boghead coal commenced to be made about 1851, and as long as true paraffin oil was the light of the people there was nothing heard of lamp accidents. When, after 10 years, petroleum commenced to be introduced in quantity, accidents and fatalities became numerous, and through scientific men writing in the newspapers, &c., a demand was made for legislation to protect the people. Our first Petroleum Act was passed in 1862. No method of testing was given, but "Petroleum for the purposes of this Act shall include any product thereof that gives off inflammable vapour at a temperature of less than 100° F." As we have seen, oil of 100° Abel test, gives off inflammable vapour in dangerous quantity at 100°, so that if our legislators had had our present knowledge, they would have fixed 100° close test as the standard, and it was, therefore, 100° close test that they meant. The words they used were a good enough definition of flash-point, but the Americans interpreted it as allowing 100° with their open firing test, which gives a point about 50° above the close test and the point of danger. The result was that oil was sent in more dangerous than before, and for awhile safe oil could no longer be got. The Act appointed no inspectors, and the law, although powerful for evil, was quite powerless for good. As a consequence, fatalities, instead of being fewer, were more numerous.

The next step was the investigation by the Select Committee of the House of Commons on Fire Protection, 1867. The evidence was printed, with a separate index. Science was faithfully represented by such men as Prof. Lyon Playfair and Dr. Atfield, and they advocated 120° open test as

the lowest standard that could with safety be adopted. Prof. Playfair represented that this standard could easily be attained in practice, and without harming the foreign petroleum trade, and this was supported by large refiners from America. The petroleum trade representatives, however, maintained that a high standard would practically shut out foreign petroleum, and declared that 100 firing-test was sufficient for safety. The Committee reported that explosions from mineral oil arose from a light being brought in contact with the vapours, and the lower the temperature at which vapours are given off, the greater the danger. So the Committee had caught quite clearly the scientific principles of the case. Trying to strike a medium between the conflicting demands as to standard, they recommended as a compromise that no coal, shale, or petroleum illuminating oils should be sold with an ignition point under 110° F., to be tested with an oil cup in a water-bath, and a light applied to the surface of the oil. Evidence had shown that Americans tested by applying the flame to the surface of the oil, but that the English petroleum tester applied the flame an inch above the surface of the oil, so the Committee evidently meant to fix us to the stricter American method.

When in 1868, these recommendations were attempted to be carried out in a Bill, the schedule descriptive of the apparatus and mode of testing was handed over to Prof. Abel, Dr. Letheby, and Prof. Atfield. They reported that the standard, instead of being 110 as recommended by the Parliamentary Committee, may be lowered to 100° if their test and method of testing be rigidly adhered to. The apparatus they recommended was to be of thin sheet iron, 3 ins. deep, $1\frac{1}{2}$ ins. diameter, with a rim at top to support it in water-bath which was $4\frac{1}{2}$ ins. deep and $4\frac{1}{2}$ ins. diameter. The petroleum is to fill the inner vessel about half full; the surface of the water in outer vessel to be at same level, and commence cold, and a small flame put below it. A thermometer in the oil is to be moved about occasionally, a small flame applied quickly close to the surface of the oil, at 90° , and tried every 5° until a flash is got; then the experiment repeated with fresh oil and cold water, beginning near the flash-point got, and applying the flame every 2° .

This apparatus will give a varying result, depending on whether in a quiet or a draughty room, whether the flame is skilfully put over the surface of the oil or put a good way above it. With oil of 73° Abel, beginning to test at 65° and testing every 5° , I get the flash at 70° , or 3° under the Abel test, every 2° it flashed at 73° . Other experimenters got results varying by 5° or so, according to skill. So this test is practically the same as the Abel test when the conditions laid down are rigidly adhered to, and all their remarks may be taken as applicable to Abel flash-point.

The old open test was put into the Bill contrary to Dr. Atfield's protest at the time; and that, without raising the standard to suit, the standard being left at 100 to suit the cup of the three chemists. The old open test gives a point 20° or 30° higher than that of the three chemists. So 100 standard crept into the Act through an egregious blunder, viz., the standard fixed with one test and a different test adopted. There has never been any scientific Government investigation which proved that 100 old open test was safe for the people, but only the investigation of the three chemists proving the very reverse.

100 old open test thus became the standard, the lowest possible point with the most unreliable instrument, and the standard has been kept at this point ever since. With the result that accidents have continued as before; but people were now satisfied that they were inevitable.

The old open test thus adopted is a very false and unscientific one. The cup is open, although oil is never burned or kept in an open vessel; and the vapours given off, instead of accumulating as in a lamp, are gradually dissipated into the atmosphere during the experiment, and the slower the temperature rises the falser is the result. Also, instead of getting the light applied to near the surface of the oil as the Americans do, the flame was not allowed to get within quarter or half-an-inch—often in practice a whole inch—a matter of considerable importance in an open test. But the test would have been passable if honestly

used, with proper stipulations as to screen, &c., if the standard had been made to suit it. The petroleum authorities, however, adopted a very low rate of heating and also a very low screen, thus "trying to get as far away from the truth as possible," as Mr. Keates, Metropolitan Inspector, boldly accused them of doing. Every time they applied the flame they passed it back and forward three times, thus cutting away the vapours, instead of quietly applying it at once. This is all distinctly brought out in the Report, Petroleum Bill, 1872. No conviction could be got under this test; a little manipulation of the breath could prove any oil safe, and there was constant conflict between the results of the Metropolitan Inspectors and the chemists employed by the Petroleum Association. It was seen at once that a close test must be adopted, and Mr. Keates's was proposed; but the question arose, what was the equivalent between the close and the open? In 1871 the Act still in operation was passed, but as no agreement could be come to between the conflicting parties as to the right point to put in for the close test, the old open test and 100° was again put in, and the Act passed for a year in the hope of an agreement. The Government did not refer the matter to any scientific authority, who could by experiment easily settle the matter for ever; they let the matter be fought out between the home trade and the foreign, neither of whom were by any means identified with the good of the people, but both had interests in common contrary to the people's. Moreover, the question was not as it should have been, what is the equivalent of 100° in the test of the three chemists? but, conserving the original blunder, what is the equivalent of 100° old open test?—a different question, and a very indefinite one. The petroleum chemists made the difference about 30° ; the home trade chemists made it about 15° . The old test had to be adopted from year to year, as no agreement was possible. It was settled in 1879 when the Abel test was adopted, when the petroleum authorities got all their own way.

In 1868 Parliamentary Committee recommended 110° open test. The three chemists recommended a test equal to 120° open test; and here we adopt 73°—not the equivalent of 100° open test, as originally intended by the Government, but even 10° under that at least.

The Government, however, saw that this was not all that was required, and they asked Prof. Abel "whether 100° F. (or its equivalent in any modified method of testing) is, in your opinion, calculated to afford adequate protection to the public without unduly interfering with or restricting the trade; if not, what alteration in this respect should be made? He answered, "There are not, in my judgment, well-established grounds for considering that the present flashing-point of 100° F. is not calculated to afford adequate protection to the public." Col. Majendie in 1894 said he wished to suspend his opinion on the flash-point and said the *onus probandi* lay with those who wish to disturb the present standard.

Before the old Parliamentary Committees there was mistaken evidence given, which was built on as facts by the Committees. For example, that, as most of the oil at present imported is under 100° flash-point, a standard of 100 would shut out practically all the oil of the people. Not one gallon of the oil would be shut out, but only the naphtha that was in it kept separate. Merchants in this country make the mistake of thinking that a low standard would be more easily kept up to by manufacturers than a high one, and that a high standard would cause constant rejection of oil and cause them trouble. The fact is, 100° flash is as easily made as 73°, and would be kept up to as certainly. American manufacturers themselves bore witness to the fact that high-flash oil could be produced easily at 1 cent. per gallon extra cost; but petroleum merchants of this country assured the Committee with confidence that if a high standard were adopted, not a barrel of oil would come in. The price then was 1s. 6d. to 3s. 6d. The cost has not been increased by 1 cent, but the price has been reduced by from 1s. to 3s., and yet the oil pours in. Events have proved a great deal of the evidence to be utterly mistaken.

Witnesses declared there was no danger at all until oil was heated to the temperature of the American firing-point,

which is 16° or 15° above the old open flash-point. Dr. Letheby (1872, p. 57) declared that he had proved that oil of 100° old open test (= 73° Abel test) could not be exploded in lamps under ordinary circumstances, by electric spark or otherwise. The evidence as to this fact was quite wrong, and no true evidence was given to rebut it.

The relationship of the Abel test to the points of danger is one easily determined by experiment, and this must be fixed once for all before the test can be of any use whatever. The Home Office, however, seem quite content to have a vague notion that the danger point for 73° oil is somewhat above 100° (Report, 1883, p. 21, § 99). Even yet they seem quite uninstructed (Report, "Petroleum," House of Commons, 1894, p. 23, § 251), and await information from interested parties (*Ibid.*, p. 13, § 93 and 96). What possible use can a test or standard be until its relationship to danger is fixed decisively from experiment by neutral scientific men or man? And whose duty is it to determine this if it is not the Home Office officials responsible for proposed Bills.

Then again, the nomenclature adopted by the Home Office leads inevitably to confusion. Petroleum is defined to mean, what is *not* petroleum in ordinary speech, but oil under 73° flash, which is generally known as spirit or naphtha, petroleum in our ordinary language being reserved for ordinary burning oil above 73° flash. Then again the term "high-test oil" is applied by the Home Office to very low-test oil, ordinary petroleum of 73° and above it. High-test oil in ordinary language is oil about a 100° flash and above it. The confusion caused by this is so great that Col. Majendie himself was confused, and in 1883 gave facts as for ordinary 73° oil, which were true only of true high-test oil above 100°; and when Captain Hope in 1894 asked a question about high-test oil he answered as for 73°, and confused Captain Hope entirely. This way of using language adds unnecessary confusion, and prevents the people and all concerned from seeing clearly the facts of the case.

There is no room for two opinions as to the fact that oil of flash-point, 73° to 83°, gives off explosive vapours at ordinary summer temperatures, and ordinary temperatures of lamps even in winter, and is therefore very dangerous, the danger approaching that of naphtha. There is no ghost or unexplained mystery about lamp explosions—vapour, air, and a flame are required. But the flash of the oil should be so high that filling the lamp when burning, carrying about, or extinguishing by blowing or turning down the wick, can be done with perfect safety. A lamp cannot explode unless the oil vapours are evolved, and the vapours are not evolved at all unless the oil is heated about the flash-point. So the standard flash-point should be fixed so high that under ordinary circumstances of climate, and lamp in passable order, the temperature of the flash-point is never reached in the lamp of the people. The standard should be as low as possible subject to this condition.

Probably every evening in London the dangerous explosive mixture is present in about a million lamps; but only in a few cases does the light get at it; and in only a few of these again is there any damage done. Only 2,000 lamp accidents that caused much harm were known of in London for 1893, only 456 fires, only 48 deaths. A very few accidents considering that the danger is so widespread. But again, all these accidents that do take place are easily preventable. With standard of 100°, no doubt the explosive mixture would occasionally be present, but in very few cases; and even of these the proportion that could get the light applied would be a very small percentage—a few cases in a million as at present—so that the danger would practically be reduced to *nil*. The argument, therefore, that so few accidents take place at present is not one that should produce contentment with the present state of matters, and the trade left burdened and hindered by danger, seeing it could be so easily cured. Accidents with high-flash oil are very rare indeed. Coal dust and wheaten flour have caused many serious explosions, yet common sense prevents us from classing coal or flour as dangerous explosives. In the same way high-flash oils that have caused three or four accidents in the last 30 years must not be classed along with dangerous low-flash petroleum that cause hundreds of

accidents every evening. And we must remember that the low quality of the oil in the market that causes the numerous deaths is not merely allowed, but is *directly created by our legislation*, because manufacturers make the oil to suit the standard, and it frees merchants and manufacturers from responsibility for the inevitable result. The object of our legislation is surely to save lives and property.

If you continue to allow oils under 100° flash, you allow oils that contain naphtha, and that could have been kept free from naphtha without any extra expense in refining.

It is as easy to keep the naphtha separate as to put it into the burning oil. Naphtha in burning oil should be counted an adulteration. We would not lose a gallon of oil by what I propose, only the household oil would be sent in safe, and would require only ordinary care, while the naphtha would come in separate, and be treated with the necessary precautions. Naphtha in this country is generally dearer than burning oil. I cannot conceive a state of matters in which it would be wise economy, either from the national or world-wide point of view, to deliberately mix naphtha with the burning oil as at present, for it makes all dangerous.

Have a truly safe standard, and let all above standard escape burdensome surveillance. It leaves the oil trade quite free, and also the trade in lamps. It causes also that the oil of the people be all safe. All that is required in the Bill is to raise the standard to 100° close test, where it was meant to be from the first, and give towns the power of regulating the storage of large quantities.

METHOD OF ANALYSIS OF ALLOYS OF LEAD, TIN, ANTIMONY, AND COPPER.

BY C. W. THOMPSON.

ANALYSES of the alloys of lead, tin, antimony, and copper are frequently required, as these alloys enter into a great variety of uses in the arts. The classification of these alloys according to their uses may be made as follows:—

1. Low grade tinfolils, alloys of lead and tin in which the tin is less than 20 per cent.
2. Solders. Alloys of lead and tin, the tin being over 20 per cent, and the alloys frequently containing small percentages of antimony.
3. Babbitt and Britannia metals. Alloys of tin, antimony, and copper.
4. Bronzes. Alloys of tin and copper.
5. Certain kinds of bearing metals. Alloys of tin, lead, antimony, and copper.
6. Type and stereotype metals. Alloys of lead, tin, and antimony.
7. Antimonial leads. Alloys of lead and antimony containing traces of copper, arsenic, nickel, and cobalt.

It is very important that correct methods for the analysis of these alloys be used. Many of the methods now in use cannot be said to give correct results, or if correct results are obtained by their use, they are so long and tedious as to be unavailable for technical purposes. We know of one case in which chemists of repute asserted that alloys containing tin and antimony could not be analysed correctly; and we may add that in metal work there is hardly any class of analyses in which more divergent results are obtained by various chemists working on identical samples. In addition to the four metals mentioned, these alloys may contain small amounts of phosphorus, arsenic, iron, nickel, and cobalt. Phosphorus is used in phosphor-bronze and similar alloys. Arsenic, nickel, and cobalt occur as impurities in antimonial leads and in stock worked up from shot residues. Iron occurs as an impurity only to a small extent and cuts no figure in the analysis unless the sample be very dirty superficially, in which case it may be purified from iron by simple melting. An experienced eye can usually detect the principal constituents of alloys of these four metals; but if the percentage present of any one metal is small it is frequently advisable to resort to qualitative tests. We give here qualitative tests, not that the experienced chemist will have any difficulty in this regard but because these tests have proved very satisfactory and rapid in our hands.

For lead dissolve in aqua regia. If much lead is present it will separate on cooling as chloride; if only a small amount is present it will be detected by the addition of four volumes of 95 per cent. alcohol. Very small percentages, i.e., under 0.50 per cent. will not be shown by this test.

For tin dissolve in HCl conc. containing some KCl, and before the portion of alloy taken is completely dissolved, pour off supernatant solution, cool to separate lead as chloride, add four volumes of alcohol, filter and to the filtrate add a slight excess of bromine water to convert SnCl_2 to SnCl_4 , heat to expel free Br, dilute and pass H_2S when if tin is present it will be obtained as yellow stannic sulphide.

For antimony treat with HCl conc. Almost all the antimony is left undissolved, decant and wash residue well with water, after which dissolve in HCl with KClO_3 , boil to expel free Cl and pass H_2S obtaining precipitate of Sb_2S_3 if antimony is present. If copper is also present, it will be precipitated as CuS and may obscure the colour of Sb_2S_3 , if so filter and treat precipitate with KOH which will dissolve the Sb_2S_3 , filter and acidify filtrate, when the pure colour of the Sb_2S_3 will be observed if antimony is present.

For copper treat with dilute nitric acid in porcelain dish, evaporate to dryness, when, if copper is present, it will show as a green ring where it crystallises out of nitrate on edge of residue.

For arsenic dissolve in HCl with addition of KClO_3 in Erlenmeyer flask, boil to expel free Cl add more HCl conc. and two (2) grms. of sodium thiosulphate, connect flask with condenser and distil, following in principle the method first proposed by Fischer. Arsenic will be found in distillate by passing H_2S . The use of sodium thiosulphate as a reducing agent in this distillation of arsenic is very satisfactory, possessing as it does the great advantage of leaving a solution suitable for further analysis. If the boiling of residual solution is carried far enough, the thiosulphate is entirely decomposed with the liberation of sulphur which can be filtered off, the only contamination to the solution then being sodium sulphate.

We determine the metals as follows:—

Lead, by precipitation as chromate in acetic acid solution after Fresenius, filtering and weighing on Gooch crucible. We have found this method the most accurate we have used. No volumetric method has as yet commended itself to us. It is frequently convenient where lead only is to be determined to work on 0.64 grm. obtaining the percentage directly in centigrams of lead chromate found.

Tin we determine electrolytically in double oxalate solution after Classen. This solution is obtained in the course of regular analysis by the systematic method given further on. Very good results are obtained.

Antimony we determine volumetrically in a strong HCl solution by reduction of the Sb_2Cl_6 to Sb_2Cl_3 by addition of

KI in excess, titrating the liberated I with thiosulphate of sodium. The method of separation described below gives us a solution of antimonious sulphide in KOH entirely free from copper and iron, and containing a minimum amount of sulphur to be subsequently oxidised or separated by filtration. To this alkaline solution we add 1 grm. of KClO_3 and 50 c.c. HCl conc. and boil until the solution is colourless and the free Cl is driven out. The solution is then cooled, 1 grm. KI added and 1 c.c. CS_2 . The thiosulphate is run in until the aqueous solution is decolourised, then drop by drop with vigorous agitation until the CS_2 is decolourised. The trouble that others have had in using this method is probably due to the imperfect separation of the copper and iron from the antimony, and the presence of a large amount of free sulphur which in strong HCl coats over the sulphide of antimony and prevents its ready solution. We obtain our antimony sulphide in the first place containing very little free sulphur and then dissolve it in a solution of KOH obtaining a complete separation from copper. We then treat this KOH solution as above.

We determine copper in small amounts by titration with KCN and in large amounts electrolytically. Arsenic can be determined by precipitation as As_2S_3 and weighing on Gooch crucible, or by titration as with antimony.

The separation of the metals in the classes of alloys we have described is based on Clark's oxalic acid method. As, however, that method is for the separation of tin from antimony and arsenic, the first thing to be determined was how far it is applicable for the separation of tin from other metals. Bismuth, copper, and cadmium oxalates are soluble in aqueous solutions of oxalic acid containing oxalate of ammonium, and the respective sulphides are obtained by passing H_2S through such solutions boiling. Lead and zinc oxalates are nearly insoluble in similar solutions, but such oxalates are more or less converted to sulphides by the passage of H_2S through the solutions in which they are suspended. As, however, copper and lead are the principal metals which it is desired to separate from tin, our experiments were principally directed towards observing their respective reactions. Working upon alloys containing large percentages of tin and small percentages of antimony and copper, dissolving in aqua regia, adding some KCl to form double chlorides, evaporating to dryness on water-bath and taking up in solution of oxalic acid containing enough oxalate of ammonium to form double oxalate of copper soluble in water, the separation of the copper and antimony from the tin is readily effected by the passage of H_2S through the solution on boiling for a sufficient length of time. After filtering out the antimony and copper sulphides we proceed to their separation. We could have used sodium sulphide of course, but its use would have resulted unsatisfactorily in the determination of the antimony volumetrically. We found the use of a solution of caustic potash more satisfactory, that reagent dissolving antimony sulphide readily. The determination of the tin in the filtrate from the sulphides of antimony and copper could be made by rendering it alkaline with ammonia and acid with acetic acid and then passing H_2S , filtering, &c., igniting and weighing as SnO_2 ; but for large amounts of tin this method was not found sufficiently accurate. Classen's electrolytic method of determination was finally adopted as giving the best results. This method consists in obtaining the tin in solution as double oxalate of tin and ammonium, with enough free oxalic acid to prevent the precipitation of stannic hydrate, and electrolysis. The presence of chlorides does not interfere with the electrolysis of the tin, as whatever chlorine is liberated at the cathode does not act upon the platinum but upon the oxalates in solution, decomposing them. If we have only tin, copper, and antimony present, what we need do, therefore, is to add such an amount of oxalic acid, oxalate of ammonium, and water to the evaporated chlorides as will give the proper solution to electrolyse after passing H_2S to precipitate antimony and copper, filtering, &c. We found that working on 1 grm. of alloy, and using 10 grms. of oxalic acid, 10 grms. of oxalate of ammonium and 200 c.c. of water, a proper solution was obtained for electrolysis.

Working upon alloys containing lead the insolubility of

lead oxalate interfered with the use of the above method. The separation of lead from antimony, tin, and copper was finally effected by its precipitation as chloride from its HCl solution first by chilling and crystallisation and then by the addition of alcohol. We were pleased to discover that this precipitation is a practically complete one in the presence of KCl, and also that the chloride of lead thus precipitated is easily washed free from chlorides of tin, antimony, and copper by the use of alcohol containing HCl. Working on 1 gram of solder, for instance, after treatment in alcohol, filtering and washing, the filtrate was found to contain only 0.30 per cent. of lead. But the use of alcohol presented a new difficulty in that it could not be entirely evaporated off by heating on the water-bath. The combination apparently formed between the alcohol and the chlorides of tin and antimony was very stable. The evil effect of alcohol was that on passing H_2S to precipitate antimony and copper, a liberation of sulphur took place that was very objectionable in that it was filtered out with the antimony sulphide and dissolved with it by the KOH, interfering with the determination of the antimony. To overcome the separation of sulphur we had recourse to the treatment of the residue left on evaporation with KOH solution and H_2O_2 . This was attended with the desired result that in the subsequent treatment with H_2S in oxalic acid solution the separation of sulphur was very slight. At this point we would mention a very peculiar thing regarding the action of H_2S on solutions of oxalate of tin. It is that the H_2S is absorbed and what might be called a sulpho-stannate is formed. That this is the case was first suggested by the fact well known that in the separation of tin and antimony the precipitation of the antimony only takes place after the tin has been fully supplied with H_2S . The time necessary to secure the complete precipitation of the antimony is proportional to the amount of tin present. That there is a sulpho compound of tin formed is further proven by the fact that during the electrolysis of the oxalic acid solution there is a separation of sulphur, although the solution had been boiled for a long time to expel H_2S .

We have described the separation of lead as chloride from the tin, antimony, and copper. The conversion of the lead chloride into soluble acetate is easily effected by treatment with ammonium acetate, after which the lead is determined as chromate in the usual manner.

We will now describe the system we have adopted for the analysis of these alloys. One gram of the finely divided alloy is dissolved by boiling in from 70 to 100 c.c. of the following solution in a covered beaker. The solution is made by dissolving 20 grms. KCl in 500 c.c. H_2O , then adding 400 c.c. HCl conc., mixing, and then 100 c.c. HNO_3 1.40 specific gravity. No decomposition between HCl and HNO_3 takes place in this solution in the cold. If complete solution of the alloy is difficult in the amount of the solution taken, more is added as required. Continue boiling until solution is evaporated to about 50 c.c. Cool by placing beaker in cold water until the bulk of the lead has crystallised out as chloride, and then add slowly and with constant stirring 100 c.c. 95 per cent. alcohol; allowed to stand about 20 minutes, filter through 9 cm. paper into No. 4 beaker, wash by decantation three times with a mixture of 95 per cent. alcohol and HCl conc., 4-1, and wash paper twice with same mixture. Wash PbCl_2 on paper back into beaker and wash paper several times with hot water, allowing washings to flow into beaker with the rest of chloride. Finally, wash twice with a solution of ammonium acetate hot (the ammonium acetate solution is made by taking one volume of ammonia water 0.900 sp. gr., adding to it one volume of water and then 80 per cent. acetic acid until it is slightly acid to litmus), heat until lead chloride is all dissolved, add 15 c.c. saturated solution of $\text{K}_2\text{Cr}_2\text{O}_7$, heat until precipitate is of good orange colour, filter on weighed Gooch crucible, wash with water, alcohol, and ether, dry at 110°C , and weigh. Evaporate the filtrate from lead chloride by heating on hot plate and finally to dryness on water-bath. Add 10 c.c. solution of KOH (1 gm. to 5 c.c.) and after a few minutes 20 c.c. of 3 per cent. peroxide of hydrogen. Heat on water-bath for 20 minutes, add 10 grms. of ammonium oxalate, 10 grms. of oxalic acid, and 200 c.c. of water. Heat to boiling, pass H_2S with solution near boiling

for 45 minutes, filter at once, and wash precipitate with hot water. Boil filtrate to expel H_2S , concentrate if necessary, and electrolyse over night, using a current of about $\frac{1}{2}$ an ampère. Usually by morning the solution will have become alkaline, in which case it may be taken for granted that the tin is all precipitated on the cylinder. The cylinder is removed, washed twice with water, and then with 95 per cent. alcohol, dried in oven, and weighed. The precipitate of antimony and copper sulphides on the filter paper is washed back into beaker with the least amount of water possible and treated with 10 cc. KOH solution (1-5), heated on water-bath until undissolved matter is distinctly black, then filtered through same paper it was washed from into 12-oz. Erlenmeyer flask, washed, &c. On filter the copper is obtained as sulphide with a small amount of lead which failed to be precipitated as chloride (if it is desired to determine this lead it can be done by separation from the copper as usual), if not, dry and ignite precipitate in small casserole, dissolve in HNO_3 , boil to expel nitrous fumes, neutralise with Na_2CO_3 , add a few drops of ammonia, and determine volumetrically with cyanide of potassium standardised against pure copper.

The solution of antimony sulphide in KOH should not amount to over 40 c.c., add 1 gm. KClO_4 , 50 c.c. HCl conc., boil until solution is colourless and free Cl is driven off, filter through mineral wool if sulphur has separated into similar flask, wash out original flask with conc. HCl, cool, add 1 gm. of KI, 1 c.c. CS_2 , and titrate for antimony with N_{10} sodium thiosulphate, 1 c.c. of which equals 0.0060 gm. antimony. This systematic method assumes the absence of other metals than lead, tin, antimony, and copper; for the determination of other metals we offer the following suggestions. If arsenic is present it will be separated with the antimony and will liberate iodine as does antimony. One c.c. of N_{10} thiosulphate equals 0.00375 gm. of arsenic.

Arsenic is preferably determined on a separate portion by dissolving in HCl and KClO_4 boiling to expel free Cl, and distilling after the addition of sodium thiosulphate as a reducing agent, passing H_2S through the distillate and weighing As_2S_3 or dissolving it in KOH, and determining volumetrically as in the case of antimony.

Bismuth and cadmium sulphides would remain with copper sulphide after treatment with KOH solution. This renders this method very suitable for the analysis of fusible metals. Zinc would interfere with this method, but as it does not alloy with the lead to any extent we will not speak of it further. Nickel and cobalt alloy but slightly with tin, and if present should be sought for both in precipitate left by KOH and in tin precipitated on cylinder. Iron will also be precipitated with tin electrolytically if present in an oxalic acid solution. Phosphorus is best determined by Dudley's method. In alloys containing only lead and tin, with the tin under 20 per cent., the two constituents can best be determined by treatment with dilute HNO_3 in porcelain dish, evaporating to dryness on water-bath, &c., and determining lead as chromate and tin as SnO_2 . In samples free from iron and copper, antimony may be determined directly by solution in HCl and KClO_4 , boiling to expel free Cl and titrating as with pure antimony. Antimony in solders may be determined very accurately by dissolving in HCl away from access of air and filtering out the undissolved antimony on weighed Gooch crucible. I have not found a weighable amount of antimony was lost as stibine by this treatment. In the analysis of alloys of lead and tin, Richards' scales, which are accurate within 1 per cent., may be used. In the examination of the various classes of alloys described at the beginning of this paper, various steps in their analysis may be left out with the absence of the respective metals.

Thus, in the absence of lead, the addition of alcohol may be omitted, and the evaporation can proceed directly to dryness after the sample is dissolved. In such a case the treatment with KOH and H_2O_2 is also omitted. In the analysis of samples high in copper, as bronzes for instance, it is not well to let the evaporation proceed quite to dryness, as in that case compounds are formed insoluble in oxalic acid and ammonium oxalate.

I give the following examples of the accuracy of this method:—

I.	Taken.	Found.
	Grms.	Grms.
Lead	0.8000	0.8045
Tin	0.0320	0.0313
Antimony	0.1000	0.0990
Copper	0.0080	0.0073

II.	Taken.	Found.
	Grms.	Grms.
Lead	0.1000	0.0988
Tin	0.0007	0.0010
Antimony	0.1000	0.0987
Copper	0.0503	0.0507

There are a few points still to be mentioned. To clean the platinum cylinders of the tin precipitated on them by electrolysis, we have found strong hydrochloric acid in the cold very satisfactory. The cylinders change very little in weight if properly cleaned. In the precipitation of the chloride of lead the acid solution should not be evaporated much below 59 c.c., and the addition of the alcohol should be very gradual, otherwise the chloride of lead precipitated will not be pure, and inaccurate results will be obtained. If a very small percentage of lead is present it is not advisable to attempt its precipitation with alcohol, but rather to let the analysis proceed as in the absence of lead, separating it subsequently from the copper by the usual methods.

LABORATORY TESTING IN CONNECTION WITH GOLD EXTRACTION.

BY A. W. WARWICK, F.R.S.

SYSTEMATIC laboratory testing as an adjunct to the miling of gold ores ought to be of supreme importance. In many gold ores which are being worked successfully the valuable portion is only 1/60,000th of the total rock handled, and but a very slight variation in the character may cause enormous losses. It is therefore obvious that a system of laboratory tests which will show with a fair degree of accuracy the conditions in which the gold is disseminated through gold-bearing rocks, can render many useful services to the metallurgist.

Laboratory metallurgy has an evil name amongst practical and business men; it is in fact impossible to express in writing the contempt which is manifested towards laboratory tests by such men. Results which are obtained by ill-conceived methods of examination and which are further degraded by reckless use, are, to be sure, of little value. It is, however, unnecessary to tell a society of technical chemists that laboratory tests used correctly and worked by methods strictly applicable to the case under consideration can be of the greatest use. For example, there are many cases in the history of gold mining in which a great deal of money and time would have been saved, if, before proceeding to work the ores, they had been subjected to a proper system of laboratory tests. It is a self-evident truism, yet, however, to be learned by many superintendents of gold mills, that information may in many cases be obtained more quickly, cheaply, and accurately in the laboratory than in the mill. It is pointed out here that the tests to be described do not aim at showing the yields that may be obtained by practical working, but rather to show defects and the remedies to be applied, and as a collateral to act as guides in designing a plant for an ore hitherto unworked and of which little is known.

Some time ago, whilst chemist in a metallurgical testing works in London, a great many parcels of gold ore passed through my hands, and in dealing with a great variety of ores a system of trustworthy laboratory tests was absolutely essential. There is to be found scattered through metallurgical literature a number of rough-and-ready tests,* but nothing which would satisfactorily answer the purpose. An account of the method of examination may therefore be of value to managers and metallurgical chemists in general.

In order to ascertain the precise character of each parcel of ore, a series of tests was drawn up to come at the following facts:—(1) The degree of crushing required to unlock the gold and gold-bearing minerals from the gangue; (2) the physical character of the wet pulp and its action upon mercury; (3) the amount of "free" readily amalgamable gold; (4) the amount of free gold incrustated with oxides, &c., i.e., rusty; (5) the amount of gold locked up in the heavy minerals and the percentage of the latter; (6) the amount of "float" gold; (7) the general character and size of the gold particles. Most if not all of these facts can be obtained by direct experiment, but it is better in the cases of rusty and float gold to obtain them indirectly.

Having come to a conclusion on these points it is possible to work out a scheme for the treatment of the ore under examination or to locate the defects in treatment if it is being worked already. It is, however, very necessary to check the results obtained in the laboratory by working a fairly large parcel of ore according to the mode of treatment shown by them to be appropriate. The results given, however, by the mill tests show a surprising concordance with the laboratory results.

The procedure adopted for any particular ore will naturally vary somewhat according to the needs of the case, but the tests described in this paper may be so varied as to meet nearly all requirements. In any case, however, it was the writer's practice to commence work on a parcel of ore by determining the facts scheduled above.

Sampling.—A little care in sampling is well repaid. "Grab" samples should be absolutely barred. More errors result from inaccurate samples than all the rest of the work put together. A sample should be made sufficiently large to suffice for all the tests to be made, so as to ensure uniformity among the results. Ten to twenty pounds is amply large enough.

Crushing.—The first point to be ascertained is the degree of fineness to which the rock should be crushed in order to unlock the gold and gold-bearing minerals. About two pounds of the rock are crushed by hand in a mortar to go through a 30-mesh screen, care being taken to prevent the formation of very fine dust. About 400 grms. of the crushed stuff are screened successively through 60- and 90-mesh screens. The percentages of each grade of ore thus made are determined. Each grade is now assayed and the amount of "free" amalgamable gold determined by the test to be described later; if the coarser sizes show a high assay value and a low amalgamation extraction, it may be safely concluded that the degree of crushing is not fine enough. In most cases it is only necessary to examine the coarsest size for amalgamable gold, as the finer sizes show usually a high amalgamation assay. An ore containing 0.639 oz. gold per ton and about 3 per cent. iron pyrites was treated in this manner, with the following results:—

Stuff passing through h	Remain- ing on.	Per- centage.	Assay Value, Ozs. per Ton.	Per Cent. of Total Ore Value.	Free Amalga- mable Gold, Ozs. per Ton.	Per Cent. of Total Ore Value.
30 screen	60 screen	29.2	0.11	3.4	0.051	1.61
60 "	90 "	50.5	0.39	30.8	0.239	18.88
90 "	"	29.3	1.42	65.6	0.563	25.81
100.0			99.8		48.30	

In this case the grade of ore between 30 and 60 screen contains but 3½ per cent. of the total value of the ore, and of that nearly one-half is recoverable by amalgamation. The balance is left in the heavy minerals and coarse particles of ore, and as it only amounts to 0.059 oz. per ton it is obvious that the crushing is fine enough for this

* These are summarised by A. G. Charlton in a paper read before the Federated Inst. Mining Engineers, Eng., in 1893.

ore, especially as some of this value is recoverable by concentration. In stating the screen required in practice some judgment is necessary, as account must be taken of the type of machine used. Rolls would require a 30 screen, and stamps 18 to 24, according to the type of the mortar; however, considerations such as these are beyond the scope of this paper. The ore just referred to was received as an example of a refractory ore, inasmuch as only about 47 per cent. was recoverable by amalgamation. On inquiry it was found that the plant consisted only of stamps and plates, as it was considered unnecessary to save the heavy minerals on account of the small percentage. The excessive loss was attributed to "float" and "rusty" gold by the management. The addition of a concentrating plant effectually cured the low extraction. This is a very good example of the need of laboratory testing in the mill; the little bill run up by the company would have purchased all the fittings and apparatus for a decent assay office.

Examination of the Pulp.—The character of the wet pulp may not only influence the laboratory tests, but it has an effect upon the milling. Thus, if it is slimy, an excessive amount of gold may be carried off by flotation. Most limonite ores have this character; on crushing such ores and moistening with water for the amalgamation assay the wet pulp has an unctuous feel; on amalgamating, the mercury is generally covered with a film resembling oil, but no sickening, properly speaking, took place. As an example an ore from Costa Rica may be given. The ore was free milling, it contained absolutely no heavy minerals, and consisted of about 30 per cent. limonite, the remaining 70 per cent. being quartz. On crushing and direct amalgamation, 25 per cent. of the gold was obtained as "free amalgamable gold." On heating to about 300° C. the ore lost 5 per cent. of moisture, and changed in colour to a dark red. On mixing with water it had lost its greasy feel and became sharp and gritty. Amalgamating now gave 73 per cent., thus showing the evil influence of slimes in preventing good contact between the mercury and gold. The character of the mineral particles should be examined. I have repeatedly noticed that when iron pyrites is hard, compact, and distinctly cubical in a gold pulp, then the amalgamating plates keep bright, and the vanner concentrates are clean and the tailings free from savable mineral. On the other hand, when the pyrites is soft and honeycombed, then the plates sicken readily, and the vanner concentrates are dirty, or the tailings contain much mineral.

Examination of Soluble Matters.—Most ores that find their way to a testing works are more or less refractory. In a great many cases the refractory nature of the ore has been traced to the soluble matters. In one case in particular an ore from the island of Borneo contained no less than 13 per cent. of soluble matters, consisting chiefly of ferrous sulphate, sulphate of alumina, and free sulphuric acid. Needless to say, the ore absolutely refused to amalgamate. Most gossan ores contain from a trace to 2 per cent. of solubles. If the ore contains more than 0.2 to 0.3 per cent. solubles, trouble may be anticipated. A qualitative analysis at least should always be made of the soluble bodies.

Amalgamation Assay.—This assay is made in order to determine the free, readily amalgamable gold—that is to say, gold which can be and should be saved by copper-plate amalgamation. The amalgamation assay as usually performed, and as described in most text-books on assaying, is useless for the purpose of a systematic examination of a gold ore, as it not only gives the free amalgamable gold, but also some of the float, rusty, and gold in heavy minerals. The simplest way to perform this test is to weigh out into a porcelain mortar 4 assay tons of ore crushed to the screen found to be the right one by the test given above. Sufficient water is added to form a very thin paste, thin enough—in fact, to prevent the mercury being broken up into small globules. An accurately weighed amount of mercury (50 to 75 grms.) is now added. The contents of the mortar are then stirred for an hour to an hour and a half with a light, hard wood pestle, care being taken not to rub the ore or break up the mercury. The paste is then further thinned with water and poured into a large basin. The mercury left behind is collected into one globule and washed. The

tailings are twice washed in a horn spoon in order to collect any mercury that may have gone with them. The tailings are kept for additional testing.

The mercury after being thoroughly washed is dried carefully, first with blotting-paper and then for a short time at 80° to 100° C. The mercury is now weighed; the loss of mercury is an excellent guide as to the degree of sickening of the amalgamated plates in mill work. According to my experience the following table gives a fair indication of the sickening likely to occur, although it may differ slightly according to the experimenter:—

Loss of Mercury.

Per Cent.	
0.1 to 0.3	Sickening inconsiderable.
0.3 to 0.5	" appreciable.
0.5 to 1.0	" excessive.
Over 1.0	Impossible to amalgamate.

The amalgam is placed in a scorifier and another scorifier is placed mouth downwards over it; they are then heated at a very low heat in a muffle until the mercury has entirely volatilised, care being taken of course that the fumes are carried off up the chimney. The covering scorifier is removed, about $\frac{3}{4}$ A.T.* granulated is sprinkled over the bottom of the lower scorifier and $\frac{1}{2}$ A.T. over the bottom of the covering scorifier; scorification is allowed to proceed for a short time, the lead run into one button and cupelled. The bead of precious metals is treated as usual. The gold obtained in this way is the free amalgamable gold, which should be caught on copper plates. Ores that sicken mercury to any considerable extent, however, require a preliminary treatment. In such a case the ore is thoroughly washed with warm water followed by a very dilute solution of $\text{NaHO}(\text{NaHO}, 100\text{OH}_2)$ to decompose basic sulphates, &c. The wash liquors are passed through a filter, and, after washing, the filter paper is burned and added to the bulk of the ore, which is then amalgamated in the manner described.

Gold in Heavy Minerals.—The tailings from the amalgamation assay are concentrated on a batea or on a vanning shovel. The heavy minerals are dried, weighed, and assayed for gold and silver. The gold and silver obtained will be the contents of the heavy minerals *plus* the "rusty" gold; it is therefore necessary, in order to determine the gold in the heavy minerals, to determine the "rusty" gold. In order to do this, 3 A.T. of ore are taken and concentrated in the same manner as the tailings. The heavy minerals are washed into a porcelain basin and treated with dilute hydrochloric acid free from chlorine; the acid is filtered off, the residue washed with water two or three times and finally with a 1 per cent. solution of KCN, the solution of KCN remaining on the residue for only a minute or two. All these wash liquors are filtered, and at the end of the operation the filter paper is burned and added to the mineral residue. The residue is amalgamated by shaking up in a bottle with mercury for half an hour, the mercury collected and treated as in the amalgamation assay. The gold obtained is the free amalgamable *plus* the rusty. Now let—

A = gold in heavy minerals *plus* rusty gold : B = free amalgamable gold : C = free amalgamable gold *plus* rusty gold : D = rusty gold : E = gold in minerals : then $D = C - B$, and $E = A - D$, all stated in ounces per ton of the original ore. Thus a sample of Transvaal bauket contained 0.83 oz. gold per ton; the free amalgamable gold was 0.57 oz.; the gold in the minerals and rusty gold together was 0.23 oz.; the free amalgamable gold and rusty together amounted to 0.61 oz.; then the rusty gold $D = 0.61 - 0.57 = 0.04$ oz. per ton, and the gold in the heavy minerals $E = 0.23 - 0.04 = 0.19$ oz. per ton of ore. In the ore in question the minerals amounted to $3\frac{1}{2}$ per cent., and if all were saved the concentrates should assay 5.42 oz. per ton.

Estimation of Float Gold.—The determination of float gold is of considerable importance, inasmuch as the word

* A.T. = assay ton.

"float" looms large in the vocabulary of the average millman. It is fairly safe to attribute losses to "float," as, so far as I am aware, no means are available for testing the amount of such gold. The amount of float gold is largely dependent upon the character of the wet pulp. Slimy pulps will carry off fine particles of gold more readily than clear gritty pulps. The amount of float is not altogether dependent upon the size of the gold particles. Several methods have been tried to obtain the amount of float gold directly, but without success; the results are in all cases too high. The only satisfactory method is to deduct from the total assay value of the ore the combined values of free amalgamable, rusty, and ore in heavy minerals. Thus in the Transvaal basket cited above the float gold would be $0.83 - (0.57 + 0.04 + 0.19) = 0.03$ oz. per ton, or 2.4 per cent. of the total value.

Attempts made to estimate the float gold by means of the elutriating apparatus used to determine sand in clays, &c., gave unsatisfactory results; in all cases the results were 10 to 20 per cent. too high when compared with the method just described.

Microscopic examination of the gold particles is sometimes of great assistance. The minerals panned out from the tailings from the amalgamation assay should always be examined under a low-power objective. Particles of gold may be frequently observed quite bright, and should have apparently been amalgamated. A little cyanide added to the minerals while yet under the microscope will generally cause the small globules of mercury, which are invariably present in the tailings from the amalgamation assay, to almost immediately coat such particles of gold with mercury. The reason for this may possibly be explained by the observation of Skey, that gold is rendered unamalgamable by treating with sulphide solutions.

All the information which can be obtained from the ore itself, and which can be of metallurgical importance, is now at hand. The application of such matter is so obvious that it will not be dealt with in this paper; yet one may be pardoned for saying that although the results obtained by these tests may be highly satisfactory, yet the local circumstances in which the ore is found may forbid the working of it. Business capacity combined with a knowledge of the locality in which the ore is found, are absolutely essential before the laboratory results can be utilised metallurgically.

The mode of procedure for testing the efficiency of a mill may vary considerably from the foregoing, although it is undoubtedly of importance to run through such a scheme whenever there is a change in the character of the ore milled. Systematic checking of the mill results should be regularly made. In order to do so, good average samples should be obtained: (1) of the rock sent to the mill; (2) from each distinct part of the mill, such as (a) from immediately below the mortar, (b) from the end of the amalgamating plates, (c) concentrates from the vanners, (d) from the mill tailings. These samples are examined according to the needs of the case by such of the foregoing tests as are applicable: for example, the tailings should be examined for loss of gold due to insufficient crushing; the loss due to "float"; the loss due to uncaught heavy minerals, and so forth. These tests, combined with good mill statistics, would result in bringing to light and locating many losses hitherto unsuspected, and would suggest the necessary remedies. More, such a system of testing would act as a detector of theft, and assist in putting down one of the most troublesome annoyances of the mill manager.

In the many cases where I have had occasion to use this system of tests, the results have been confirmed in every possible way, and left no doubt of their accuracy.

In every case where a divergence from the laboratory results was noticed, the error was due, not to the laboratory tests, but to the mill work. The figures obtained from the assay for the "free amalgamable" gold described above agree in a very remarkable manner with the amount of gold actually saved by copper plates in the mill; a divergence of 25 per cent. was obtained in one case, but on examination of the concentrates made on fine vanners, quite large flakes of gold were found, which were thoroughly coated with mercury; it was evident that either the plates had too much pitch or too much water was used; in fact, both too

much water and too much pitch were the disturbing influences.

These tests have been described chiefly from the point of view of the treatment of the so-called free milling ores, but the writer is of opinion that they can be of service in a great many cases outside of this view, by making necessary modifications.

In most mills of the West there is a good deal of unnecessary hurry to get the ore through the mill into the tailing dump. Systematic tests are rarely, if ever, performed. Hence it is that every now and again parties buy up mill dumps and get profitable returns. This is, to a large extent, due to the cent-wise dollar-foolish policy of mill proprietors who begrudge decent accommodation to the assayer. In one of the largest mills of the West, splendidly equipped with work-shops, &c., the assay office is small, inconvenient, and worse fitted up for its purpose than the blacksmith's shop. In another fine mill which is kept in a trim in every way creditable to its superintendent, there is actually no assay office at all. There is little or no doubt that with proper appliances and a system of test, as outlined in this paper, a great deal of waste and loss that now goes on can be very largely obviated.

DISCUSSION.

The CHAIRMAN said that in the Bulletin No. 3 of the California States Mining Bureau, Mr. Ed. B. Preston called attention to the old practice of relying upon rule of thumb tests. The mill manager by the horn spoon test was supposed to know how much the ore would mill to the ton, and if the horn spoon tests of the tailings showed no amalgam, he thought all was being saved. It was not sufficient to know that a certain loss had been sustained, but one must know at what particular part of the operation the loss had been incurred, hence the necessity of constant sampling and assaying by an expert.

Mr. MURRAY EDWARDS said that the best evidence as to the necessity of employing skilled chemists was to be found in the results obtained at the mines in South Africa. After many years working in a crude way without expert aid, skilled chemists were engaged, and the cyanide process adopted, so that in 1893 gold to the value of 6,610,000 dols. was extracted from refuse which had been thrown away. In August 1894, 1,160,000 dols. resulted from one month's work, 60 per cent. from current work, and 40 per cent. from refuse. The cyanide process had been previously tried without success, because there was no chemist to work it. When the chemist set to work he found the tailings had been lying so long that the pyrites had decomposed, and presented difficulties which he was able to overcome.

Mr. H. VAN HOEVENBERGH exhibited and explained a new petroleum lamp with automatic lighting arrangement.

Dr. R. C. SCHIFFRINUS exhibited and explained a modified separating funnel and an extracting apparatus adapted for the analysis of smokeless powder. In the various connections corks had to be used, which solvents such as alcohol, ether, and chloroform destroyed. Soaking the corks in a solution of gelatine mixed with formaldehyde resisted these solvents, but not acetone, which apparently dissolved everything.

The CHAIRMAN introduced the subject of Röntgen's rays. Drs. Stebbins, Wainwright, McKenna, and Schweitzer took part in the discussion. It was suggested that the investigation of these phenomena might utilise the services of chemists in the preparation of special plates to receive the shadows, and that it would open up new fields of research to the metallurgist and to the engineer.

PATENTS.

Revolving Retorts for Furnaces, Improvements in. J. A. Yeaton and W. Adgie, both of Leeds. Eng. Pat. 104, Jan. 2, 1895.

THE improvement claimed relates to patents (Eng. Pat. 19,183, 1889; this Journal, 1890, 797; and Eng. Pat. 5239, 1892; this Journal, 1893, 439) previously granted to the same inventors, and consists in corrugating the revolving body of the retort. The corrugations may be either parallel to the axis of rotation, or helical.—R. B. P.

Evaporating and Distilling Liquids, Improvements in Apparatus for. A. A. Robin, Paris. Eng. Pat. 2424, Feb. 4, 1895.

THIS invention relates to the construction and arrangement of a low-pressure still for the distillation of volatile compounds, and more particularly of such as are inflammable, a number of applications being quoted. It may also be used for the extraction of oils or fatty substances. It consists essentially of four parts: a water-bath in a tank K, an evaporating pan, a condenser C, and a receiver E. The water-bath is heated to a constant temperature by gas or other suitable means, and is provided with an overflow D. The evaporator, or in a modification, the water-bath carrying the evaporator, is levelled by screws V. The condenser, having a conical bottom and a conical top, is provided with a rim at S, which dips into a mercury or plastic seal, with handles A, and with a central opening H for introducing fresh cold water. Through the bottoms of the tank and the evaporator passes a tube O, which leads the distillate into the receiver E. The tube O is surrounded by two lengths of tube M, between which is placed mercury or other non-volatile liquid, or some plastic material, as putty or wax, so as to form a seal into which dips the tube O, projecting downwards from the bell-mouth of the tube O. The surface of the bath-liquid B is covered

with an insoluble light non-volatile liquid, as petroleum. The graduated gauge or receiver E is surrounded with ice

or a current of cold water, and rests upon a disc Q, supported upon a spring Z, so that by depressing the receiver, the pipe O may be withdrawn therefrom.—R. S.

Evaporating Apparatus [Multiple-Effect], Improvements in and relating to. J. Foster, Glasgow. Eng. Pat. 3118, Feb. 13, 1895.

THIS invention relates particularly to multiple-effect apparatus of the vertical type for evaporating sugar juice and like liquors, in which the evaporators are arranged in steps. Each evaporator consists of a chamber provided with two cross plates, one near the bottom, the other nearly half-way up, connected by tubes through which the juice passes, delivered over the top plate and flowing downwards, while the steam is admitted to the space surrounding the tubes. The improvements consist of the following:—1st. The ports for admitting steam consist of a number of openings arranged in two or more horizontal rows, or, in a modification of a series of single vertical parallel slotted branches. 2nd. The juice is delivered on to the top plate by means of a main trunk tube passing across the evaporator, from which proceeds on each side a series of parallel horizontal tubes immediately over the rows of vertical evaporating tubes, and are provided with short vertical branch tubes leading into the latter. 3rd. Each vertical evaporating tube is provided with two juice or liquor spreaders or distributors, one at the top of each tube and one between the upper and lower tube plates, so as to direct the juice to the surface of the tubes. 4th. Instead of the spreader between the tube plates, a zinc tube may be fitted within each tube concentric therewith, such zinc tube having a series of conoidal or tapering annular shields, and openings through which the vapour from the juice escapes, and passing upwards assists in evaporating the juices, thus producing a double evaporating effect. 5th. When the inner tubes are used, a special tapering shield is arranged at the top of each tube for directing and regulating the flow of juice and permitting the escape of vapour. These shields are carried by rods which pass downwards through the tubes and all rest upon a plate which can be raised or lowered, so as to regulate the shields, by means of external screws.—R. S.

Double-Tube Boilers, Evaporators, and other Heat Exchangers, Improvements in. K. D. Noble, Helensburgh, and J. Irving, Cardross. Eng. Pat. 4831, March 7, 1895.

THE boilers, evaporators, and other heat exchangers are provided with a stack of inclined double tubes. The inner and longer tube of each pair is secured to outer tube plates, whilst the outer and shorter tube of each pair is secured to inner tube plates, the space at each end between the two

* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to Sir Henry Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

tube plates forming a water chest. These water chests are connected by the annular spaces between the inner and outer tubes of each pair, and are also put into connection with a highly-placed steam drum or cylinder from which downward circulating tubes lead to a low-placed horizontal tube or cylinder connected to the lower water chest, thereby completing the circulation. The furnace is below the stack, and the fire gases, after passing around the outsides of the tubes, pass to a space above, and thence to the back of the lower water chest, through the inner tube of each pair, and out to the stack.

Evaporating Apparatus [Multiple-Effect], Improvements in. J. B. Elliott, Nottingham. Eng. Pat. 5496, March 15, 1895.

One or more preliminary evaporators are employed, which are heated by high-pressure steam, and are used in connection with one evaporator, or with a battery of multiple-effect evaporators heated by low-pressure exhaust steam. The preliminary evaporator is provided with a reducing valve so adjusted as to feed the steam to the main evaporator, or to the first vessel of the battery, at the same pressure as that of the exhaust steam with which it mingles. It has also a safety valve.—R. S.

Furnaces [Carbon Pencils] for Continuous Use, Improvements in. H. Niewerth and R. Niewerth, Berlin. Eng. Pat. 3559, Feb. 19, 1895.

Two furnaces are described and illustrated: first, a multiple arrangement, and second, a single furnace. The multiple arrangement consists of four chambers or ovens placed one above the other, and connected to a common grate, with suitable flues and dampers, so that the fire can be passed into the different chambers at will, thereby allowing continuous work to be done. Such a battery of furnaces is particularly suitable for baking or burning carbon pencils for arc lamps. For some articles it is desirable to gradually allow them to cool in the oven before removing them; for this purpose, air passages having dampers are provided. The single furnace shown is also specially designed for baking carbon pencils, but without using crucibles as at present. The improvement consists in the shape of the hearth, which is formed as a shallow receptacle in which the rods may be embedded in carbon dust or other material to prevent them sticking to one another.—R. S.

Mica and Mica-Ore Purifying and Pulverising, Improvements in or relating to Methods of and Apparatus for. A. J. Boulton, London. From T. J. Lovett, Chicago, U.S. Eng. Pat. 19,892, Oct. 22, 1895.

FINELY-DIVIDED mica is a valuable ingredient of axle-grease and other lubricating materials, but hitherto the difficulty of producing fine division of this tough and lamellar substance, and of separating it from gritty matter, have restricted its use, and have prevented the use of the commoner kinds. In the present invention, the commoner kinds of mica are first reduced to a state of moderately fine division, which gives the mica in flakes and the impurities in fine grit. A blast of air, assisted in its action by the swirl or eddy caused by a diaphragm, is then directed upon the material, with the result that the grit is blown through the meshes of a sieve. The flakes of mica, which remain, are then allowed to slide down a screen which acts as a shoot to these flakes, but allows any grit that may be left to drop through the meshes. The further reduction of the purified flakes of mica to a sufficiently fine state of division is effected by a machine which acts by cutting and tearing rather than by grinding and pounding.—V. C.

Furnaces [Metallurgical, Glass, &c.], Improvements in. E. Powell, Pittsburgh, U.S.A. Eng. Pat. 24,214, Dec. 17, 1895.

This invention is applicable to furnaces for the evolution of heat from fuel in the various descriptions of heating apparatus employed in manufacturing or mechanical operations, and for the generation of steam. It consists in providing the fuel chamber, which is closed above and below to access of air, with an adjustable air-supply

passage at one side above the firebed, and on the opposite side with (a) an exit throat or passage at or near its firebed, and (b) one or more gas conduits above the layer of fuel. The passages lead the gases to a combustion chamber, either meeting one another before reaching such chamber or discharging thereinto one above the other, but in either case the gases evolved from the incandescent portion of the fuel of a downward-draught furnace, and the smoke and partially consumed gases from the top of the fuel of such a furnace, meet at a point wholly exterior to the fuel chamber, thereby producing a flame of great intensity in the combustion chamber. The invention is illustrated as applied to a metallurgical furnace and to a glass furnace.—R. S.

II.—FUEL, GAS, AND LIGHT.

Coals, The Caking Power of. L. Campredon. Rev. Chim. Indust. 1896, 7, 8.

To determine the caking power of a coal, the sample is ground sufficiently fine to pass through a sieve of 400 holes per square centimetre. It is then diluted with varying proportions of fine dry sand and the mixture ignited in a covered crucible, the character of the resulting coke being noted. The weight of the coal being taken as unity, the largest amount of sand that the sample will bear and yet give a coherent coke represents the caking power of the coal. In the case of some Welsh coals, the coke takes the form of a powder without the addition of any diluent; therefore the number found on examining different samples may vary from 0 to 17.

It should be noted that mere exposure to the atmosphere affects this property of coal; at elevated temperatures the loss of caking power is still more rapid. There does not, however, seem to be any connection between the quantity of volatile matter in the sample and its caking power—as is shown in the following table:—

Sample.	Volatile Matter.	Ash.	Coke.	Caking Power.
Welsh coal (Aberdare)	10.90	6.20	82.90	0
Newcastle coal	34.25	10.89	54.95	2
Scotch coal	34.72	8.35	56.93	4
Welsh coal (Cardiff)	19.80	7.70	72.50	6
Lens coal (Pas-de-Calais)	27.20	8.70	64.10	13
Lens coal heated to 110° C. for one year.	28.12	8.55	63.33	0
Gas coal (Newcastle)	27.83	8.75	63.42	14
.....	29.50	8.50	62.00	17
Pitch (Beckton)	44.82	0.60	54.58	20

Coals, Determination of their Heating Effects. W. A. Noyes, J. R. McTaggart, and H. W. Craven. J. Amer. Chem. Soc. 1895, 17, 843—849.

REFERENCES are given to the recorded discrepancies found by Schenck-Kestner and others to exist between the calculated and the determined calorific powers of coals. The authors have tested six specimens of representative Indiana coals by the Hempel calorimeter, by Berthier's test, and by analysis; two of these coals (Brazil and Lancaster) are non-caking, and are known as block coals, whilst the other four are bituminous caking coals. Anthracite could not be compressed into cylinders for the calorimeter, and could not be burned as a powder; it was therefore not tested. The moisture was found by drying at 105° C. for an hour in a toluene bath, and the fixed carbon by heating 1 grm. of the coal in a covered platinum crucible with the full flame of a Bunsen burner for seven minutes; the oxygen was estimated by difference, after adding to the weight of ash found, five-eighths of the weight of sulphur present, as the sulphur generally occurs in the form of pyrites, which is assumed to be burned to Fe_2O_3 and SO_2 . The calorific power is calculated from the formula $8080\text{C} + 28,800(\text{H} - \frac{1}{8}\text{O}) + 1582\text{Fe} + 2168\text{S}$, the symbols standing for the weight of the corresponding elements present, and hydrogen being supposed burnt to vapour of water. In the Hempel calorimeter the thermometer was

read by means of a telescope, and the rise of temperature was only 5° in each experiment, so that the error due to radiation was minimised; the error produced by the condensation of the water vapour formed during combustion is corrected in the results recorded, by deducting 610 calories per gram. of water formed, assuming the calorimeter temperature to be 26° C. The Berthier test was made by mixing 1 gram. of coal with 40 grms. of litharge in a Battersa C crucible, and there covering it with a layer of salt. The covered crucible was placed in a hot gas furnace for

15 or 20 minutes; it was then removed, tapped to collect the lead, cooled, and broken, and the lead was cleaned and weighed. Theoretically 1 gram. of lead should correspond to a heating effect of 234 calories in the coal, but the average of the results obtained gave an empirical factor of 268·3 calories per gram. of lead, and this number is used in stating the results. In all cases the results are the means of at least three concordant experiments. The methods employed in the tests are fully described in the paper; the results are as follows:—

	Non-caking "Block" Coal.		Bituminous Caking Coal.			
	Lancaster.	Brazil.	New Pittsburg.		Shelburn.	Mine Screenings.
			A.	B.		
Moisture	12·66	8·98	6·83	5·89	8·63	2·36

Calories per gram. (Berthier)	6831	6689	6367	6471	6461	5726
Difference, per cent.	+ 1·9	- 2·3	+ 2·1	+ 0·9	- 1·1	- 1·4
Calories per gram. (calorimeter)	6793	6846	6175	6415	6532	5806

The calorimeter results represent most accurately the relative heating value of the coals; but the results calculated from analysis and those found by Berthier's test agree better with each other than either agrees with the calorimeter results; but the Berthier results on the average are the better of the two. Attempts to use the calorimeter of Barrus failed, owing to a deposit of carbon being always formed.—W. G. M.

Waste of Heat in the Generation and Use of Steam, Some Preventable. W. Kent. Journ. Franklin Inst. 1895, 140, 406—419.

THEORETICALLY, 1 lb. of good anthracite coal should be capable of evaporating about 15 lb. of water from and at 212°, whilst a good bituminous coal should evaporate about 15·5 lb. of water under like conditions. The maximum efficiency obtained with a good boiler, well set, and well stoked with good anthracite coal is about 80 per cent. of the theoretical, whilst the efficiency is less with bituminous coal, owing to the difficulty of burning the gases generated at a low temperature when fresh coal is put on the fire. The unpreventable loss when using anthracite coal is principally due to the fact that it is not practicable to reduce the temperature in the flues to less than about 100° F. above the steam temperature, or below 400°, to 450°, though probably some of this loss might be saved by utilising this waste heat to heat the feed water. But in very many boilers far more than this 20 per cent. of theoretical heat is lost, and this further loss is preventable. The sources of this preventable waste are many, of which the following are the chief:—

Improper Burning of the Coal.—The bed of coal may be too thick for the draught available, when there is incomplete combustion, and unburned carbonic oxide escapes and is lost or on the other hand, the bed of coal may be too shallow for the draught, when excess of air passes through, with consequent chilling. The use of generators and separate combustion chambers with superheated secondary air supplies, much economises the coal.

Waste in the Boiler.—The heating surface may be too small—at least 1 sq. ft. of heating surface should be allowed for every 3 lb. of water to be evaporated per hour—or the surface may be inefficiently placed for receiving the heating gases. The unclean condition of the inside or outside of the boiler is, also often the cause of loss. Leaky blow-off valves, excess of pressure and consequent blowing

off of steam at safety valve are also frequent causes of loss.

Waste in Steam Pipes.—Uncovered piping causes great loss by radiation of heat. Experiments have shown a loss of one horse-power for 132 ft. length of uncovered 2-in. pipe, for 46 ft. of 6-in. pipe, and for 26 ft. of 12-in. pipe.

Waste in Engine.—The following table gives the approximate amounts of water consumed per horse-power per hour in various types of engines:—

Common direct-acting pump.....	100 lb. and upwards.
Old style slow-speed throttling engine, non-condensing.....	45 "
Modern high-speed, automatic cut-off	30 "
Compound	22 "
Corliss single-cylinder high-pressure	20 "
Corliss single-cylinder, high-pressure condensing	18 "
Corliss compound high-pressure	14 "
" triple-expansion condensing.....	12½ "

These losses are due to (i.) condensation of the steam as it enters the cylinder; (ii.) waste of steam in engines which are overloaded, due to exhausting the steam at too high terminal pressure; (iii.) waste of steam in high-pressure engines which are not sufficiently loaded, by exhausting the steam below atmospheric pressure. The last two sources of waste can be reduced to a minimum only by properly proportioning the engine to the work to be done. The waste from cylinder condensation is best saved by triple-expansion engines, and the position of the cut-off is very important. In single-cylinder high-pressure engines the maximum efficiency is obtained when the cut-off is between one-quarter and one-fifth of the stroke. The best engines use about 12½ lb. steam per horse-power per hour, or give only about 18·7 per cent. of the theoretical efficiency, and taking the boiler efficiency as 80 per cent., we get the maximum efficiency of the boiler and engine as 15 per cent., or about one-seventh of the heating value of the coal used.

Coal-Gas, Relative Proportions of Sulphurous and Sulphuric Acids formed during and after Combustion of. M. Dennstedt and C. Ahrens. Zeits. anal. Chem. 1896, 35, 1—10.

COLLAX has described a process for determining SO₂ and SO₃ in the combustion products of coal-gas (this Journal, 1895, 771), and concludes that almost the whole of the

sulphur is converted during combustion into SO_2 , and remains as such in the atmosphere. This conclusion the authors cannot confirm. According to their experiments, the proportion of SO_2 produced in the flame itself is, indeed, comparatively small (7–8 per cent.), although it varies to some extent with the rate of air supply during combustion. However, this point is of no particular importance, since it is shown that the SO_2 , after leaving the flame, suffers, in presence of atmospheric oxygen and moisture, continual further oxidation to sulphuric acid; and the authors believe that under favourable conditions (such as obtain when gas burns in the open air) this oxidation would be completed in a very short space of time. This conclusion, which is opposed to the generally accepted belief, makes additionally evident the necessity of removing as completely as possible all sulphur compounds from coal-gas. As regards Collan's analytical process (absorption in standard chromic acid and final titration of the unreduced portion), it appears that it yields erroneous results owing to the presence of other reducing bodies besides SO_2 .

Acetylene from Calcium Carbide, Separation of Phosphoretted Hydrogen from; the Preparation of Pure Silver Acetylide, Silver Nitrate, &c. C. Willgerodt. Ber. 1895, 28, 2107–2115.

CALCIUM phosphide is present as an impurity in calcium carbide when this substance is prepared from material containing calcium phosphate, and the decomposition of such carbide with water gives an acetylene containing phosphoretted hydrogen. The presence of this latter may be detected by the odour of the evolved gas and the precipitation of dark-coloured silver phosphide when the gas is conducted into silver nitrate solution. To estimate the phosphoretted hydrogen the author decomposed 10 grms. of the carbide and led the evolved gas through a series of three flasks containing bromine water, by which means the phosphorus compounds were converted to phosphoric acid, which was estimated. 10 grms. calcium carbide gave 0.0065 gm. Mg_3P_2 ; this is equivalent to 65 c.c. P_2H_4 per 1 kilo. of carbide.

Acetylene silver, silver nitrate, $\text{HC}\equiv\text{C}\cdot\text{Ag}\cdot\text{AgNO}_3$.—This compound is prepared by conducting the gas, evolved from carbide, into a series of flasks containing a solution of silver nitrate in water. All phosphorus compounds are removed in the first flask and the acetylide separates in the succeeding vessels as a pure white powder, which, if dried in the dark, remains white for a considerable time. Heated in a melting-point tube (in quantities not exceeding 5 mgrms.) the appearance changes visibly at 170°C , and the colour becomes darker and darker with increasing temperature up to 230°C , when explosion occurs.

By friction or concussion the substance explodes violently, with separation of carbon, silver, and silver oxide, and great care is required in handling it.

Analysis gave 70.86 per cent. Ag (theory = 71.28 per cent.). The compound is stable in the air and becomes perfectly dry when left exposed to the atmosphere. Treatment with hydrochloric acid liberates acetylene gas, and on boiling, the silver is completely removed as chloride.

Acetylene, Combustion of. H. Le Chatelier. Comptes rend. 1895, 121, 1144–1147.

MIXTURES of acetylene with air are explosive when they contain more than 2.8 and less than 65 per cent. of acetylene, mixtures of acetylene and oxygen when they contain more than 2.8 and less than 93 per cent. of acetylene. In tubes of less diameter than about 40 mm., these limits are gradually narrowed, until in tubes of 0.5 mm. the propagation of the flame ceases altogether. In mixtures of air and acetylene, when the acetylene is less than 7.7 per cent. the flame is yellowish-brown and feebly luminous, and the products of combustion are carbonic anhydride and water. When the acetylene amounts to from 7.7 to 17.4 per cent., the flame is pale blue with a yellowish-brown edge, and carbonic anhydride, carbonic oxide, and water are formed. Between 17.4 and 20 per cent. of acetylene cause very imperfect combustion, carbonic oxide, hydrogen, carbon, and

acetylene being amongst the products, whilst when the hydrocarbon exceeds 20 per cent., the deposition of soot is very marked, and the flame, though strongly luminous, is of a reddish colour.

The rate of propagation of the flame is 0.1 metre per second with 2.9 per cent. of acetylene, increases rapidly to 5 metres with 8 per cent., still increases slowly to 6 metres with 9–19 per cent., and then decreases rapidly to 0.4 metre with 22 per cent., and slowly to 0.05 metre with 64 per cent. The temperature of ignition is very low, viz., about 480°C , most other combustible gases requiring a temperature of 600°C for ignition. The temperature of the flame is very high, owing to the endothermic character of acetylene. Burned with its own volume of oxygen, acetylene gives a temperature of about $4,000^\circ\text{C}$, or nearly $1,000^\circ\text{C}$ more than that given by the oxyhydrogen flame.—L. T. T.

Luminosity, Acetylene Theory of. Vivian B. Lewes.

Proc. Chem. Soc. 1895, [159], 1–8.

THE author considers that the criticism offered against the acetylene theory by Smithells (Trans. Chem. Soc. 1895, 67, 1049, and this Journal, 1895, 1037) in no way affects the considerations upon which the theory is based, which are—

1. That the unsaturated hydrocarbons in the inner region of the flame are largely converted into acetylene before luminosity commences.

2. That acetylene develops luminosity when heated whilst flowing through a hard glass tube, no air being present.

3. That the temperature necessary to decompose acetylene with evolution of light does not raise to incandescence the carbon liberated by the decomposition.

4. That in luminous hydrocarbon flames of sufficiently high temperature the luminosity varies directly with the amount of acetylene present at the point where luminosity commences.

The objections raised by Smithells against the determination of absolute temperatures in flames by means of the Le Chatelier thermo-couple are warmly endorsed by the author as far as those portions are concerned in which combustion is taking place, and these objections were pointed out in his former paper (this Journal, 1895, 738), but he contends that the results obtained in the inner non-luminous portion of a hydrocarbon flame are probably fairly accurate, and the results obtained by Smithells confirm the statement that the temperature in the inner zone rises from a comparatively low temperature close to the burner to over $1,000^\circ\text{C}$ at the apex of the cone.

The author describes experiments showing that although the heat of combustion of acetylene is very high, so small a proportion has to be burnt in order to develop the remaining energy as light and radiant heat, that it by no means follows that the acetylene flame is hotter, or even as hot, as a coal-gas or ethylene flame of the same size.

Smithells concludes that the statement that cyanogen could be made to undergo luminous combustion has arisen from a yellow ammonia flame having been mistaken for one containing solid carbon; the author shows that by surrounding the cyanogen flame by nitric oxide, intense luminosity and a copious deposit of soot can be obtained.

The author contends that the flame is in reality divided into two zones—

1. The outer sheath of combustion,
2. The inner region of non-combustion,

and that the latter consists of an internal portion in which radiant heat is converting the hydrocarbons into acetylene; a luminous envelope which caps it, and in which more intense heat is decomposing the acetylene with emission of light, and the blue calyx at the bottom of the inner zone where the hydrocarbons are undergoing decomposition by water vapour and carbon dioxide without previous separation of carbon.

The author also contends that the incandescent carbon particles in the upper portion of the flame are acted upon by carbon dioxide and water vapour, forming carbon monoxide and hydrogen, and that this action tends far more than combustion by the air, to prevent their escape from the flame.

Prof. Smithells, in reply, said the question was not whether the explanation of luminosity afforded by the acetylene

theory was conceivable, but whether the theory was really in harmony with ascertained facts, and this question, he still thought, was to be answered decidedly in the negative.

He wished that Lewes would state explicitly what view he had as to the structure of an ordinary gas flame. Did he, or did he not accept the old and generally accepted view, that the flame consisted of three distinct parts—a luminous region, a mantle, and a blue calyx at the base? Lewes had attempted to define the parts of flame by reference to temperatures; and whereas at one time he indicated the mantle as the region of lowest temperature, he now appeared to agree that it was the hottest part. Did he still maintain temperature measurements to be a reasonable basis for defining the anatomy of the flame?

He did not consider that Lewes had explained the extraordinary discrepancies that had been pointed out in his measurements of temperature, and he should like to know whether Lewes had used the thermo-couple, as shown in the apparatus before them, or whether he had not, as implied in his previous papers, inserted the twist of the thermo-couple in a manner now admitted to be improper.

He still thought that it was misleading to speak of 80 per cent. of the unsaturated hydrocarbons as being converted into acetylene within the flame. If acetylene were the source of light, and if the light depended on the almost explosive character of its decomposition, there surely was some reason to ask for evidence that a mixture of gases containing 1·4 per cent. of acetylene, 0·5 per cent. of other unsaturated hydrocarbons, and 98 per cent. of other gases (four-fifths of which were incombustible) could afford light in the manner stated.

There was no getting over the fact that the acetylene flame was surrounded by a mantle of extremely high temperature, and that a platinum wire introduced into it glowed at least as brightly as the carbon within the flame. That being the case, there was no occasion to explain that, hypothetically, the flame might be cool.
